17 **Short summary:** We show that cold acclimation is common in Pooideae, but that this adaptation to
18 temperate climate largely has evolved independently in different tribes.

19 **Author contributions:** All authors designed the experiment. M.S. and S.F. performed the growth
20 experiments. M.S. sampled and prepared RNA for sequencing, helped designing the data analysis pipeline,
21 contributed to the positive selection analysis and performed the phylogenetic analyses. L.G. developed,
22 implemented and conducted the transcriptome data analyses. All authors interpreted the results and wrote
23 the manuscript.

24 **Funding information:** The research was funded by grants from the Nansen Foundation to S.F. and the
25 TVERRforsk program at the Norwegian University of Life Sciences (NMBU) to S.F., T.R.H. and S.R.S.
26 This work was part of the PhD projects of M.S. and L.G. funded by NMBU.

31 Abstract

32 The grass subfamily Pooideae dominates the grass floras in temperate regions, and has evolved complex
33 physiological adaptations to cope with environments characterized by extreme conditions like frost, winter
34 and strong seasonality. One such adaptation is cold acclimation, where plants increase their frost tolerance
35 in response to gradually falling temperatures and shorter days in the autumn. However, understanding how
36 complex traits like cold acclimation evolve through adaptive changes remains a major challenge in
37 evolutionary biology.

38 Here, we investigate the evolution of cold acclimation in Pooideae, and test a phylogenetically diverse set
39 of Pooideae species for cold acclimation capacity. To establish if the underlying genetic basis is shared, we
40 assembled transcriptomes of five phylogenetically diverse species and compared differential expression
41 after short- and long-term cold treatment. Furthermore, we studied the association between evolution of
42 gene family size and selection pressure on coding sequence with gene cold responsiveness.

43 All species have cold acclimation capacity, but the underlying genetic responses reflect widespread species-
44 specific cold responses in genes with conserved sequence. We saw evidence of protein coding sequence
45 and regulatory evolution, as well as the origin of novel genes and functions playing a role in cold response
46 evolution in Pooideae.

47 Our results are consistent with phylogenetic dating and paleoclimatic data suggesting that selection pressure
48 resulting from dramatic global cooling must have acted on already diverged lineages. However, phylogeny-
49 wide conservation of certain genes indicate that the Pooideae ancestor may have possessed some molecular
50 machinery to mitigate cold stress.

51 Introduction

52 Frost is one of the most dramatic abiotic stresses a plant can experience and exposure to frost is limiting
53 the opportunity for many species to diversify in temperate and arctic regions. Only a few, ancestrally
54 tropical angiosperm lineages have colonized temperate biomes (Judd et al., 1994; Wiens and Donoghue
55 2004; Kerkhoff et al., 2014). These lineages represent several independent transitions from tropical to
56 temperate environments and represent a variety of evolutionary adaptations to both unpredictable, short
57 incidences of episodic frost and predictable periods of periodic frosts (i.e. winter). Today's cold climate is
58 the result of gradual cooling over the last 50 million years (my), and the temperate biomes originated
59 relatively recently in Earth's history when the global climate started to cool in the late Eocene (Potts and
60 Behrensmeyer, 1992; Morley, 2000; Zachos et al., 2001; Fine and Ree, 2006; Eldrett et al., 2009; Liu et al.,
61 2009; Strömberg, 2011). Around the Eocene-Oligocene (E-O) transition 34 my ago, global temperatures
62 fell dramatically (Pound and Salzmann, 2017). Throughout the Oligocene the temperatures continued to
63 drop and together with increased seasonality (Zachos et al., 2001; Eldrett et al., 2009) this triggered the
64 expansion of temperate biomes to intensify. The successful colonizers of the emerging temperate climates
65 faced gradually more severe stresses and evolved adaptations to frost, increased temperature seasonality,
66 and short growing seasons (Zachos et al., 2001; Eldrett et al., 2009; Mudelsee et al., 2014). The fact that
67 only a restricted number of plant lineages have transitioned into the temperate region suggests that it is
68 challenging to evolve the coordinated set of physiological changes needed to withstand low temperatures
69 (Donoghue, 2008).

70 The capacity for surviving environments with sub-zero temperatures depends on acquisition of frost
71 tolerance. Most importantly, plants need to maintain the integrity of cell membranes to avoid osmotic stress
72 during prolonged freezing (Thomashow, 1999). To endure predictable, periodic frost, plants must have
73 evolved to integrate both phenology and complex physiological adjustments. Through a process called cold

74 acclimation, freezing tolerance is acquired through a range of physiological changes governed by diverse
75 molecular pathways. These changes result in an increase in the sugar content of cells, change in lipid
76 composition of membranes and synthesis of anti-freeze proteins (Janska et al., 2010; Preston and Sandve,
77 2013). In addition, low non-freezing temperatures may affect plant cells by decreasing metabolic turnover
78 rates, inhibiting the photosynthetic machinery and decreasing stability of biomolecules (e.g. lipid
79 membranes) (Sandve et al., 2011; Crosatti et al., 2013). Temperate and arctic plants use the gradually lower
80 temperature and day-length in the autumn as cues to initiate cold acclimation.

81 In the grass family (Poaceae), the subfamily Pooideae is the one occupying the coldest climate space
82 (Edwards and Smith, 2010). Except for a few hundred species in early diverging Pooideae tribes, most of
83 the ca. 4200 Pooideae species belong to the species-rich ‘core Pooideae’ clade (sensu Davis and Soreng,
84 1993; Soreng and Davis, 1998). The closest sister group to the core Pooideae is the tribe Brachypodieae,
85 which contains the model grass *Brachypodium distachyon* (Soreng et al., 2015). Because core Pooideae
86 contain economically important species like wheat (*Triticum aestivum*) and barley (*Hordeum vulgare*) as
87 well as several forage grasses like ryegrass (*Lolium perenne*) there is extensive knowledge about
88 physiological and molecular mechanisms underlying frost tolerance, however, only from a limited number
89 of core Pooideae species (e.g. Thomashow, 1999; Sandve et al., 2008; Galiba et al., 2009; Sandve et al.,
90 2011, Preston and Sandve 2013; Fjellheim et al., 2014; McKeown et al., 2016; Woods et al., 2016;
91 McKeown et al., 2017). It has been shown in numerous studies that several species of the core Pooideae
92 have the capacity to cold acclimate. Facilitating these responses are, among others, five gene families
93 known to play important roles during cold-stress response and cold acclimation in core Pooideae. These
94 gene families code for C-repeat binding factors (CBF), dehydrins (DHN), chloroplast-targeted cold-
95 regulated proteins (ctCOR), ice recrystallization inhibition proteins (IRIP) and fructosyl transferases (FST).
96 (CBF: Badawi et al., 2007; Li et al., 2012. DHN: Olave-Concha et al., 2004; Rorat, 2006; Kosová et al.,
97 2007; 2014. ctCOR: Gray et al., 1997; Crosatti et al., 1999; 2013; Tsvetanov et al., 2000. IRIP: Antikainen
98 and Griffith 1997; Hisano et al., 2004; Kumble et al., 2008; Sandve et al., 2008; John et al., 2009; Zhang et
99 al., 2010; Sandve et al., 2011. FST: Hisano et al., 2004; Tamura et al., 2014).

100 Although Pooideae species dominate temperate and arctic grass floras (Hartley, 1973; Visser et al., 2014),
101 the ancestors of this group were most likely adapted to tropical or subtropical climates (Bouchenak-Khelladi
102 et al., 2010; Strömberg 2011). Pooideae originated in the late Cretaceous or early Paleogene period
103 (Bouchenak-Khelladi et al., 2010; Christin et al., 2014; Spriggs et al., 2014; Schubert et al., 2018) during a
104 time where the global climate in general was warm (Zachos et al., 2001; Mudelsee et al., 2014) and
105 seasonality in temperature relatively low (Archibald et al., 2010). The colonization of temperate biomes by
106 Pooideae was likely facilitated by evolution of successful adaptations to cold conditions. Although studies
107 have inferred adaptation to cooler environments at the base of the Pooideae phylogeny (Edwards and Smith,
108 2010; Schubert et al., 2018), it is still not known whether the Pooideae’s most recent common ancestor
109 already was adapted to cold and/or freezing conditions, or if adaptations to cold evolved during
110 diversification of Pooideae along with falling temperatures throughout the Cenozoic and expansion of
111 temperate biomes.

112 In this paper, we aim to investigate the evolution of frost tolerance in response to cold acclimation in the
113 grass subfamily Pooideae. We first conduct classical cold acclimation and freezing test experiments to
114 determine if cold acclimation is a shared trait throughout the Pooideae phylogeny. Next, we take advantage
115 of comparative transcriptomics analyses to investigate if a shared molecular basis of cold acclimation in
116 Pooideae is present. Finally, we interpret our results in a phylogenetic and paleoclimatic context, and
117 suggest a model of mostly independent evolution of cold acclimation responses.

118 Results

119 Cold acclimation exists in early diverging lineages

120 We conducted a classical cold acclimation and freezing test experiment in nine species that represent major,
121 species rich clades in the Pooideae subfamily or belong to very early diverging lineages (Fig. 1A), and that
122 are distributed in areas where they are regularly exposed to cold, sub-zero temperatures (Fig. 1B). Freezing
123 tests revealed that cold acclimation, i.e. increased frost tolerance through exposure to cold non-freezing
124 periods, exists both in core Pooideae and species of early diverging lineages (Fig. 2). All acclimated plants
125 exhibited higher regrowth capacity at -4 and -8°C compared to non-acclimated plants, although the increase
126 in regrowth capacity was not significant at -4°C for *S. lagascae* and *N. stricta*. Non-acclimated plants of
127 early diverging Pooideae species performed better at -4°C than non-acclimated *Brachypodium* species and
128 *H. vulgare*, and comparable with the regrowth capacity of non-acclimated plants of the perennial core
129 Pooideae species *L. perenne* and *Elymus repens*.

130 *De novo* transcriptome assembly identified 8633 high confidence ortholog groups

131 To investigate the molecular basis of cold response evolution, we sampled leaf material from five species
132 spanning early to later diverging Pooideae lineages before and after subjecting them to a drop in temperature
133 and shorter days (Fig. S1). The transcriptome of each species was assembled *de novo* from RNA-sequencing
134 (RNA-Seq) reads (Table S1). Ortholog groups (OGs) were inferred by using protein sequences from the
135 five *de novo* assemblies and the reference genomes of *L. perenne*, *H. vulgare*, *B. distachyon*, *Oryza sativa*,
136 *Sorghum bicolor* and *Zea mays*. A set of 8633 high confidence ortholog groups (HCOGs) was identified
137 after filtering based on gene tree topology and species representation (Table S2).

138 Shared cold response genes included known abiotic stress genes

139 To investigate shared expression patterns across species, we constructed a single cross-species gene
140 expression table with HCOGs as rows and samples as columns - by summing the expression values of
141 monophyletic paralogs and setting the expression of missing orthologs to zero (Table S3). After removing
142 differences in mean expression levels between species for each gene, clustering reconstructed a tree with
143 replicates, and then time points, grouping together (Fig. S2A). The fact that time points mostly clustered
144 before species indicated a common transcriptional response to cold across species. An exception was time
145 points W4 and W9, which tended to cluster together and by species, indicating that responses after 4 and 9
146 weeks were very similar. We also observed a clear effect of the diurnal rhythm, with time points sampled
147 in the morning (W0, W4 and W9) forming one cluster and time points sampled in the afternoon (D0 and
148 D1) forming another.

149 Next, we focused on the short- and long-term cold response by analyzing changes in gene expression from
150 before cold treatment to eight hours (short-term) and 4-9 weeks (long-term) of cold treatment. For all
151 species pairs, there was a low, but statistically significant, correlation between expression changes after
152 cold treatment of orthologs in HCOGs (Fig. S2B). This indicates that orthologs tending to change
153 expression in the same direction after cold treatment, an observation that explains the clustering of samples
154 according to treatment before species (Fig. S2A). Finally, we analyzed the statistical significance of
155 expression change after cold treatment by classifying each individual gene as either differentially expressed
156 or not (FDR adjusted p-value < 0.05 and fold change > 2 or < 0.5, Table S4). Although a considerable
157 number of genes responded to cold in each species (1000-3000 genes), the overlap between species were
158 low. Of the 5577 HCOGs with at least one differentially expressed gene (DEG), 50% contained only one
159 DEG and thus represented orthologs differentially expressed in only one species. 31% contained DEGs
160 from two species, 14% from three species and only 4% contained DEGs from four species. Importantly,
161 this pattern was independent of expression level and did not change for the subsets of HCOGs with medium

162 or high expression (Table S4). Sixteen genes shared the same cold response (either short- or long-term) in
163 the same direction (either up or down) in all five species (Table 1). These genes thus represent strong
164 candidates for responses to cold that might have been conserved throughout the evolution of Pooideae. Nine
165 of these genes belonged to families known to be involved in cold stress or other abiotic stress responses in
166 other plant species. Of the sixteen conserved genes, 12 genes displayed short-term up regulation indicating
167 that stress response, as opposed to long-term acclimation response, is potentially more conserved.

168 We compared our DEGs to a compilation of 55 *H. vulgare* genes shown to be responsive to low temperature
169 in several previous microarray experiments (Greenup et al., 2011). We could map 33 of these genes to
170 unique OGs, of which 11 were HCOGs. We observed significant similarity in cold response between the
171 33 previously identified cold response genes and the short-term DEGs in our data ($P < 0.05$, Fig. S3). This
172 similarity was statistically significant for all five species, although noticeably larger in *H. vulgare* than in
173 the other species. This comparison thus shows that our transcriptome data was consistent with previous
174 findings in *H. vulgare*, and that cold response genes identified in *H. vulgare* exhibit some cold response in
175 other Pooideae.

176 Biological processes involved in cold response

177 To identify biological processes that evolved regulation at different stages of Pooideae speciation, we
178 targeted gene sets that were exclusively differentially expressed in all species within a clade in the
179 phylogenetic tree (i.e. branch specific DEGs), and tested these for enrichment of Gene Ontology (GO)
180 biological process annotations (Fig. 3A). For the genes that were differentially expressed in all our species
181 (Pooideae base [PB]), we found that up-regulated genes were enriched for GO annotations related to signal
182 transduction (two pseudo response regulators and diacylglycerol kinase 2 (*DGK2*)) and abiotic stimulus
183 (*Gigantea*, *LEA-14*, *DnaJ* and *DGK2*), while down-regulated genes were enriched for photosynthesis and
184 metabolism. For the genes that were exclusively differentially expressed in all species except *N. stricta*
185 (early split [ES]), down-regulated genes were again enriched for metabolism and photosynthesis.

186 Positive selection in cold responsive genes

187 To resolve the uncertain placement of Meliceae and Stipeae lineages within the Pooideae species tree we
188 reconstructed gene trees using the 3914 HCOGs with exactly one sequence from each of the five Pooideae
189 species and rice. In the most common gene tree topology, *S. lagascae* and *M. nutans* formed a monophyletic
190 clade (755 trees), but topologies where either *M. nutans* or *S. lagascae* diverged first (434 and 271 trees,
191 respectively) were also common (Fig. S4). Averaging the posterior probabilities of the branches leading to
192 the MRCA of *S. lagascae* and *M. nutans* did not produce significant support for any of the four most
193 common topologies. Thus, we displayed the relationships of Meliceae and Stipeae tribes as unresolved
194 trichotomy in Fig. 3 and 4, which is congruent with 1460 of the gene trees.

195 We also tested for positive selection (i.e. selection for beneficial substitutions) in coding sequences at each
196 of the internal branches of the species tree. The tests were only performed on the branches where the
197 respective HCOG gene tree topology was compatible with the species tree topology. 16-18% of the HCOGs
198 showed significant signs of positive selection ($P < 0.05$) depending on the branch (Fig. 3B). Next, we tested
199 for overrepresentation of positive selection among the branch specific DEGs. Although not statistically
200 significant, there was a tendency that gain of cold response was associated with positive selection on coding
201 sequence at the early (ES) and late split (LS) branches ($P = 0.077$ and $P = 0.072$, respectively) (Fig. 3B).
202 This observation indicates that both selection on regulatory as well as protein coding sequence may have
203 played a role in evolving cold responses in Pooideae.

204

205 Cold acclimation gene families have diverse evolutionary histories

206 Of the 33 previously described cold responsive *H. vulgare* genes that were also differentially expressed in
207 our experiment (Fig. S3), as many as 22 were not included in the HCOGs, mainly because they belonged
208 to gene families with complex gene duplication histories in lineages leading up to two or more of our studied
209 species. Next, we tested if this was a general trend for all cold responsive genes. This analysis showed that
210 cold responsive genes in general are members of larger gene families than genes that do not respond to
211 cold, with the exception of short-term down-regulated genes (Fig. S5). Conversely, short-term down-
212 regulated genes were enriched in single-copy gene families while up-regulated genes were less common in
213 these families (Fig. S5). We also tested if response to cold was associated with the age of the gene family
214 through a phylostratigraphic analysis. The general trend was that cold-responsive genes tended to be
215 underrepresented among the most ancient families (Fig. S6).

216 We conducted detailed analyses of five of the best studied cold acclimation gene families coding for C-
217 repeat binding factors (CBF), dehydrins (DHN), chloroplast-targeted cold-regulated proteins (ctCOR), ice
218 recrystallization inhibition proteins (IRIP) and fructosyl transferases (FST). We reconstructed gene trees
219 for these families (Fig. S7-S14) using reference sequences and *de novo* assembled transcripts (Table S5),
220 and overlaid information on short- and long-term cold response DEGs. Dehydrin genes are well studied in
221 *H. vulgare* with 13 known dehydrin homologs (termed HvDHN1 to HvDHN13). Structurally they can be
222 grouped into four distinct types based on the presence of amino acid segments (Y, K and S): SK₃-type
223 (HvDHN8), KS-type (HvDHN13), K_n-type (HvDHN5) and Y_nSK_n-type dehydrins (the 10 remaining
224 HvDHN homologs) (Kosová et al. 2007). Because the genes for these four groups represent
225 phylogenetically distinct clades (Karami et al. 2013), we reconstructed individual gene trees for each group,
226 however not for HvDHN5, because homologs were only found in the *H. vulgare* transcriptome. Two groups
227 of CBF genes – CBFIIIc/d and CBFIV – are especially important for cold acclimation in Pooideae and are
228 restricted to this subfamily (Badawi et al. 2007, Li et al. 2012). As the CBF gene family is large and highly
229 complex, we restricted our analyses of the CBF gene family to these two groups. Our analyses could not
230 completely resolve the topologies for most of the gene trees owing to their complex evolutionary history.
231 We identified, however, that DHN8, DHN13 of the DHN gene family and the ctCOR gene family as likely
232 candidates for conserved cold acclimation genes within the Pooideae (Fig. 4). Also, the expansion of the
233 CBFIIIc/d group likely started in the earliest Pooideae lineage. In contrast, the evolution of the IRI and FST
234 motifs, the expansion of the CBFIV group and the evolution of DHN5 (no tree reconstructed) was restricted
235 to later diverging lineages. Furthermore, these detailed analyses revealed a decreasing similarity in
236 transcriptional cold response with increasing phylogenetic distance (Fig. 4). Naturally, this analysis is
237 biased towards *H. vulgare* as most of what we know about these gene families is derived from crop species.

238 Discussion

239 Cold acclimation evolved independently in separate lineages

240 It has been suggested that the ecological success of the Pooideae subfamily in the northern temperate
241 regions critically relies on adaptations to cold temperatures. Here we show that cold acclimation increased
242 frost tolerance relative to non-acclimated plants in all the major Pooideae lineages (Fig. 2). This
243 demonstrates that the cold acclimation trait is pervasive across Pooideae, and an important part of
244 adaptation to a life in temperate and arctic biomes.

245 To dissect the molecular basis of the cold acclimation responses and determine if the cold acclimation
246 response has a shared molecular basis, we conducted a global comparative, transcriptomic analysis for five
247 phylogenetically diverse species. For each species, 10-30% of the highly conserved genes (i.e. genes in the
248 8,633 HCOGs) responded to cold, which is in line with what we know about cold acclimation programs

249 from other species (e.g. *Arabidopsis* (Park et al., 2015)). Transcripts involved in photosynthesis and
250 response to abiotic stimuli were significantly enriched among the genes with cold response in all species
251 (Fig. 3A). It is known that down-regulation of the photosynthetic machinery during cold temperatures is
252 one mechanism to prevent photoinhibition (Crosatti et al., 2013) and cellular damage. This protective
253 mechanism might therefore have existed early in the evolution of Pooideae. Enrichment of genes involved
254 in photosynthesis among differentially expressed genes is not specific to cold stress, but can be found as
255 response to other stresses as well, among them salt stress (Yamamoto et al., 2015) as well as heat and
256 drought stress (Liu et al., 2015). Interestingly, in our study nearly half of all cold responsive genes were
257 species-specific in differential expression tests (Table S4). This pattern was also supported by low (although
258 significant) correlations in gene expression fold-changes (Fig. S2B). These results indicate that evolution
259 of cold acclimation evolved at least partly independently in separate lineages and are in line with recent
260 work on transcriptional responses to vernalization in Pooideae (McKeown et al., 2016; Zhong et al., 2018).

261 Many genes previously associated with cold acclimation belong to complex gene families (Thomashow,
262 1999; Sandve and Fjellheim, 2010) and are therefore not included in the global analysis of highly conserved
263 orthologs. We therefore conducted an in-depth analyses of gene families known to be important for cold
264 acclimation (Fig. 4, Fig. S7-14) in well studied core Pooideae species (Choi et al., 2002; Vágújfalvi et al.,
265 2003; Badawi et al., 2007; Knox et al., 2008; Zhang et al., 2010; Livingston et al., 2009; Knox et al., 2010;
266 Soltesz et al., 2013; Jeknić et al., 2014; Todorovska et al., 2014; Marozsán-Tóth et al., 2015). The lack of
267 conserved expression patterns of these genes across the tested Pooideae species (Fig. 4) further supports
268 that cold acclimation is regulated differently in the five Pooideae species.

269 Three gene families or gene family members known to be involved in cold acclimation in core Pooideae
270 crop species evolved *de novo* or evolved a new function in some lineages. Firstly, the *FST* gene family
271 originated at the base of the core Pooideae (Fig. S14). Secondly, the functional domain of the *IRIP*-gene
272 family evolved at the base of core Pooideae/*Brachypodium* (Fig. S13). Lastly, in the *DHN* gene family the
273 gene *DHN5* evolved in Triticeae (Fig. 4). Together, these three examples provide conclusive evidence that
274 the cold acclimation responses in early diverging lineages at least partly rely on other genes and mechanisms
275 than the core Pooideae and *Brachypodium*. Some very likely candidates for cold responses specific to early
276 diverging Pooideae lineages are homologs of the Y_nSK_n -type *DHN* genes in the *DHN* family (Fig. 4, Fig.
277 S11). Y_nSK_n -type *DHN* genes are neither known to be involved in cold acclimation of *Brachypodium* and
278 core Pooideae, nor have we found any support for that in our data.

279 Even though our analyses show that the species largely follow independent evolutionary trajectories, the
280 responses to a large extent build on a common genetic basis. The CBF, DHN and COR gene families are
281 known to be involved in cold stress adaptation across the plant kingdom (Thomashow 2001; Rorat 2006)
282 and *FST* genes has evolved several times from vacuolar invertases independently across the angiosperms
283 (Vijn and Smeekens 1999). This indicate that some genes code for proteins with biochemical functions
284 suited to be recruited for cold stress mitigation. One gene family whose function in cold acclimation might
285 be conserved throughout the Pooideae is the *ctCOR* gene family (Fig. 4, Fig. S12), rendering this gene
286 family an interesting candidate that could constitute a shared molecular basis of the cold acclimation trait
287 in Pooideae. Interestingly, a *ctCOR* homolog is upregulated as response to short-term cold in rice
288 (Maruyama et al., 2014), indicating that the co-option of this gene to the highly specialized cold acclimation
289 pathway in Pooideae build on a stress response to cold that is conserved well beyond Pooideae. A very
290 similar scenario is likely for the two genes *DHN8* and *DHN13*. Homologs of both genes are induced during
291 chilling stress in rice (Aguan et al., 1991; Lee et al., 2005) and there is strong support for both genes having
292 a function in cold acclimation of core Pooideae (Kosová et al., 2007). Our results suggest that *DHN8* and
293 *DHN13* are single copy genes involved in cold acclimation in all but one investigated species.

294 Although the molecular mechanisms behind adaptive evolution is still an active field of research, it is now
295 indisputably established that novel gene regulation plays a crucial role (Romero et al., 2012). The evolution
296 of gene regulation proceeds by altering non-coding regulatory sequences in the genome, such as (cis-)
297 regulatory element (Wittkopp et al., 2012), or by altering the coding sequences of regulatory proteins. The
298 high number of genes with species-specific cold responses observed in this study is consistent with the
299 recruitment of genes with existing cold tolerance functions by means of regulatory evolution. However,
300 previous studies have also pointed to the evolution of coding sequences (Vigeland et al., 2013) as underlying
301 the acquisition of cold tolerance in Pooideae. To investigate possible adaptive evolution in coding regions,
302 we tested for the enrichment of positive selection among branch specific cold responsive genes (Fig. 3B).
303 Although not statistically significant ($P = 0.07$), increased signals for positive selection on coding
304 sequences was observed for cold responsive genes in a period of gradual cooling preceding the E-O event.
305 In conclusion, we find evidence to support that increased selection for protein coding sequence, changes in
306 gene regulation as well as novel genes and functions play a role in evolution of cold responses in Pooideae.

307 In general, it is important to note that lack of shared signals between lineages can also arise for other reasons
308 than biological meaningful differences and must therefore be interpreted with caution. In our study, limited
309 statistical power and the use of *de novo* transcriptomes could impact our ability to detect overlap in cold
310 responses between species. To minimize the effect of these putative biases in this study we only analysed
311 ortholog groups containing genes that could be assembled across all species in the phylogeny, ensuring that
312 we measured changes in gene expression levels and not changes in gene content. Furthermore, since three
313 of the species lacked reference genomes, we employed a *de novo* assembly pipeline to reconstruct the
314 transcriptomes. We showed that this pipeline could recover a set of *H. vulgare* genes previously identified
315 as cold responsive (Greenup et al., 2011) and that most of these genes were also cold responsive in *H.*
316 *vulgare* in our experiment (Greenup et al., 2011). Moreover, we conducted analyses to assess if sequencing
317 depth was a significant factor in our ability to identify shared patterns of differential expression (Table S4).
318 These results clearly show that sequencing coverage cannot explain the high ratio of lineage-specific cold
319 acclimation responses, indicating that increasing the statistical power will not change the conclusions of
320 this study. Hence, the global trend of low levels of shared cold acclimation responses is unlikely to be
321 methodological artefact, and consistent with the evolution of cold tolerance mechanisms being shaped
322 mostly independently in the different Pooideae lineages.

323 [A shared adaptive potential for evolution of cold adaptation](#)

324 Our differential expression analysis revealed 16 genes sharing cold associated gene expression shifts across
325 all species (Table 1). An overwhelming majority (12/16) of the conserved genes were short-term cold
326 responsive (Table 1) and this observation suggests that existing stress genes have been the first to be co-
327 opted into the cold response program. Ten of these genes have previously been shown to be regulated by
328 other abiotic and biotic stressors (Table 1). Nine of these conserved cold response genes are involved in
329 response to abiotic stresses in other plants, such as osmotic stress and drought. The *SNAC1-like/NAC*
330 *transcription factor 67* is one example, with homologs induced by osmotic stress in the three monocots
331 *Musa × paradisiaca* (Negi et al., 2015; Yang et al., 2015), *Oryza sativa* (Nakashima et al., 2012) and
332 *Triticum aestivum* (Mao et al., 2014). Co-option of such genes into a cold-responsive pathway might have
333 been the key to acquire cold tolerance. Some responses may be even more ancient than the MRCA of the
334 Pooideae, as some of the genes with cold response in all five species are also expressed in response to cold
335 in other species (Table 1), amongst them rice, which is a related tropical species with some tolerance to
336 chilling stress (Wang et al., 2016). Shaar-Moshe et al., (2017) recently identified *B. distachyon* genes
337 induced by drought, high salinity or heat as well as by their combinatorial effects. All genes from Table 1
338 were differentially expressed in at least one of their stress conditions. Noticeably however, none of those
339 genes was responsive to drought stress alone. We also found that cold responsive genes are

340 underrepresented among the most ancient gene families (Fig. S6). Taken together, it seems as the
341 transcriptional cold responses that are shared across the Pooideae phylogeny represent deeply conserved
342 ancestral responses to mitigate general cellular stress, rather than representing specific adaptations to
343 prepare for periodic frost.

344 Pooideae lineages evolved specific cold adaptation by expanding gene families

345 Gene family expansion has previously been suggested to play a role in cold adaptation in Pooideae (Sandve
346 and Fjellheim 2010; Li et al., 2012). As previously discussed, the conservative filtering of ortholog groups
347 employed in this study removed complex gene families containing duplication events shared by two or
348 more species. A majority of the previously described *H. vulgare* cold responsive genes (Greenup et al.,
349 2011) belonged to gene families with complex gene duplications histories. Moreover, an analysis of all cold
350 responsive genes confirmed a positive association between gene family size and cold response in our data,
351 with the exception of short-term down-regulated genes which instead were enriched among single copy
352 gene families (Fig. S5). These results thus confirm previous findings that stress related genes are enriched
353 in fast evolving gene families (Panchy et al., 2016). The gene trees of the gene families targeted for
354 phylogenetic analyses (Fig. 4, Fig. S7-14) displayed several duplication events and gene family expansions.
355 Based on our results we propose that gene family expansion was an important mode of cold adaptation in
356 the Pooideae subfamily. Our results corroborate findings from Sandve and Fjellheim (2010), who identified
357 an increase of gene copy number in the *CBFIV* group and the *FST* and *IRIP* gene families as an evolutionary
358 force of cold climate adaptation of core Pooideae and *Brachypodium* species. Although we lack sufficient
359 genomic data for early diverging Pooideae species, we found evidence for Pooideae specific expansions in
360 the *CBFIII*d group the *ctCOR* gene family and in Y_nSK_n -type *DHN* genes. Expansion of gene families may
361 have led to functional specialization or novel functions of the various gene copies. Other studies have shown
362 that stress related gene families tend to expand via tandem duplications (Hanada et al., 2008), which may
363 lead to lineage-specific expansion of the gene family (Lespinet et al., 2002). Although *de novo* assembly of
364 transcriptomes from short-read RNA-Seq data is a powerful tool that has vastly expanded the number of
365 target species for conducting transcriptomic analysis, the approach has limited power to distinguish highly
366 similar transcripts such as paralogs. Homologous genes might exist in early diverging Pooideae species,
367 but may not be expressed. Furthermore, coding sequences may contain insufficient informative
368 substitutions to reconstruct the true species topology. Further insight into the role of gene duplication events
369 in evolution of the Pooideae cold adaptation would therefore benefit immensely from additional reference
370 genomes.

371 Evolution of cold adaptation in a paleoclimatic context

372 At face value, the most striking result from our study is the presence of cold acclimation capacity in all our
373 study species, and at the same time a generally low similarity between the species in transcriptomic
374 responses to cold acclimation, as well as the presence of well described cold acclimation genes, such as
375 *FSTs*, *DHN5* and functional *IRIP*, in only some of the species. However, in a phylogenetic and
376 paleoclimatic context, these contrasting patterns can easily be reconciled. A recent study by Schubert et al.
377 (2018) places the divergence of all study species well before the E-O transition, when the global climate
378 was warm, seasonality low and temperate biomes had yet to expand. Thus, the most likely scenario is that
379 our study species have experienced >45 million years of independent evolution, and that adaptations to
380 periodic frost have independent evolutionary origins.

381 Responding to episodic and periodic frost are two fundamentally different physiological processes (Körner,
382 2016). Episodic frost induces a stress response and such existing responses could be exploited to tackle
383 frost when first experienced by the plants in the cooling climate during Eocene. On the other hand,
384 responses to periodic frost require controlled changes in cellular components initiated by plants upon

385 sensing shortening photoperiod and lower temperatures in the autumn. This complex response must have
386 evolved over a long period of evolutionary time, during which the plants were exposed to increasingly more
387 severe winters, exerting selection pressure for the cold acclimation response. Ancestral state reconstructions
388 of climatic niches of Pooideae species suggest that severe winter was not encountered by the Pooideae
389 ancestor, but was first experienced by Pooideae species more recently in the evolutionary history (Schubert
390 et al., 2018). Based on phylogenetic and paleoclimatic data we would therefore expect that selection
391 pressure for adaptations to winter seasons and frost spells across the Pooideae phylogeny would result in
392 independent evolution of cold acclimation capacity and many lineage and species specific gene expression
393 responses, as shown by our analyses.

394 Nevertheless, ancestral state reconstruction of the climatic niche of the ancestor shows that it likely
395 experienced episodic incidents of frost and that Pooideae possibly originated in a temperate micro-niche in
396 emerging alpine orogenies (Schubert et al., 2018). The conserved set of stress response genes identified in
397 our comparative transcriptome analysis may have represented a first tool-kit to cope with frost stress. This
398 may have represented a fitness advantage for the Pooideae ancestor in the newly emerging environment
399 with incidents of mild frost, allowing time to evolve the more complex physiological adaptations required
400 to endure the temperate climate with strong seasonality and cold winters that emerged following the E-O
401 transition (Eldrett et al., 2009). Thus, preadaptations to temperate climate may have given Pooideae species
402 the advantage to expand and diversify with the expanding temperate biomes after the E-O transition, while
403 gradually building more complex adaptations to cold. This is in line with Schubert et al. (2018) that show
404 that diversification rates in Pooideae is inversely correlated with temperature.

405 Materials and Methods

406 Plant material

407 Seeds from nine Pooideae species were acquired from germplasm collections or collected in nature. The
408 selected species represent major, species rich clades in the Pooideae subfamily, or belong to very early
409 diverging lineages (Soreng et al., 2015). All species are distributed in areas where they are regularly
410 exposed to cold, sub-zero temperatures. Furthermore, to ensure that the accessions of the wild species that
411 were used in the experiment are adapted to cold conditions, accessions were selected from localities with
412 cold winters (mean temperature of the coldest quarter is below zero degrees, data extracted from the
413 WorldClim v.1.4 dataset (Hijmans et al., 2005) (Fig. S15A).

414 *Nardus stricta* L. ($2n=2x=26$) is a perennial species, distributed in Europe, western parts of Asia, and North
415 Africa and introduced to New Zealand and North America (Tutin, 1980; Hultén and Fries, 1986; Clayton
416 et al., 2006). Seeds were collected in July 2012 in Romania, [46.69098 N, 22.58302 E]. The locality of the
417 collected accession experiences sub-zero temperatures in November - March and the mean temperature of
418 the coldest quarter is -3°C (Fig. S15B).

419 *Stipa lagascae* Roem and Schult. ($2n=2x=22$) is a perennial species that is distributed in temperate regions
420 around the Mediterranean Sea and parts of temperate West Asia (Tutin, 1980; Hultén and Fries, 1986;
421 Clayton et al., 2006). Seeds from accession PI 250751 were acquired from U.S. National Plant Germplasm
422 System (U.S.-NPGS) via Germplasm Resources Information Network (GRIN). The accession was collected
423 49 km northwest of Tabriz, Iran in 1958. The locality of the collected accession experiences sub-zero
424 temperatures in December - March and the mean temperature of the coldest quarter is -0.2°C (Fig. S15B).

425 *Melica nutans* L. ($2n=2x=18$) is a perennial species distributed in temperate parts of Eurasia (Tutin, 1980;
426 Hultén and Fries, 1986; Clayton et al., 2006). Seeds were collected in Germany, [50.70708 N, 11.23838 E],

427 in June 2012. The locality of the collected accession experiences sub-zero temperatures in December -
428 March and the mean temperature of the coldest quarter is -0.9°C (Fig. S15B).

429 *Brachypodium distachyon* (L.) P. Beauv. ($2n=2x=10$) is an annual species natively distributed in Europe,
430 East Africa and temperate parts of West Asia (Tutin, 1980; Hultén and Fries, 1986; Clayton et al., 2006).
431 Seeds for accession ‘Bd1-1’ (W6 46201) were acquired from U.S.-NPGS via GRIN. This accession is a
432 singel-seed descent inbred line of the accession PI170218 (U.S.-NPGS, GRIN) collected in Soma, Manisa,
433 Turkey in 1948. The line is classified as a winter variety, i.e. Bd1-1 requires vernalization to flower and it
434 is freeze tolerant (Colton-Gagnon et al., 2014).

435 *B. pinnatum* (L.) P. Beauv. ($2n=28$) is a perennial species distributed in temperate parts of Eurasia (Tutin,
436 1980; Hultén and Fries, 1986; Clayton et al., 2006). Seeds were collected in October 2015, Norway
437 [59.71861 N, 10.59333 E]. The locality of the collected material experience sub-zero temperatures in
438 November - March, and the mean temperature of the coldest quarter is -3.0°C (Fig. S15B).

439 *B. sylvaticum* (Huds.) P. Beauv. ($2n=2x=18$) is a perennial species distributed in temperate parts of Eurasia
440 (Tutin, 1980; Hultén and Fries, 1986; Clayton et al., 2006). Seeds were collected in October 2015, Norway
441 [59.68697 N, 10.61012 E]. The locality of the collected material experience sub-zero temperatures in
442 November - March, and the mean temperature of the coldest quarter is -3.2°C (Fig. S15B).

443 *Hordeum vulgare* L. ($2n=2x=14$) seeds for cultivar ‘Igri’ were provided by Prof. Åsmund Bjørnstad,
444 Department of Plant Sciences, Norwegian University of Life Sciences, Norway. Igri is a two-row winter
445 barley developed in Germany in 1976 and is much used across Western Europe (Fischbeck, 2003). Igri
446 requires vernalization to flower and is tolerant to frost (Kosová et al., 2010). Sonja is a two-row winter
447 barley developed in Germany in 1974 (Fischbeck, 2003).

448 *Lolium perenne* L. seed for cultivar ‘Fagerlin’ were provided by Dr. Kovi, Department of Plant Sciences,
449 Norwegian University of Life Sciences, Norway. Fagerlin is a winter-hardy cultivar developed in Norway
450 in 2008.

451 *Elymus repens* (L.) Gould. ($2n=4x\ 6x=28\ 42$) is a perennial species distributed in Europe and Northern
452 parts of Asia and is introduced to North America (Tutin, 1980; Hultén and Fries, 1986; Clayton et al., 2006).
453 Seeds were collected in October 2015, Norway [59.66111 N, 10.89194 E]. The locality of the collected
454 material experience sub-zero temperatures in November - March, and the mean temperature of the coldest
455 quarter is -3.1°C (Fig. S15B).

456 Freezing tests

457 Seeds from all nine species (see Plant material, for *Hordeum vulgare* the ‘Sonja’ cultivar was used) were
458 germinated and plants grown in the green house at 20°C under natural day light. Each individual was
459 divided into four clones, one for each treatment and control. The plants were acclimated at 4°C and short
460 (8h) days for three weeks. Control conditions were short days and 20°C . The light intensity was $50\ \mu\text{mol}$
461 $\text{m}^{-2}\ \text{s}^{-1}$. At the end of the cold acclimation period, plants were subjected to freezing at three different
462 temperatures (-4 , -8 and -12°C) following Alm et al., (2011). For each temperature we used 15 acclimated
463 and 15 non-acclimated individuals per species. After freezing, plants were cut down to approximately 3 cm
464 and grown at 20°C under long days in a greenhouse with natural light conditions. Two and three weeks
465 after the plants were moved into 20°C and long days they were assessed for regeneration ability and scored
466 from 0 (dead) to 9 (growth without damage). Differences between acclimated and non-acclimated
467 individuals within each species were tested with a one-tailed t test in R (R Core Team 2016) using the ‘stats’
468 package.

469 Cold treatment: Sampling, RNA extraction and sequencing

470 Seeds from *N. stricta*, *M. nutans*, *S. lagascae*, *B. distachyon* and *Hordeum vulgare* (cultivar ‘Igri’) were
471 germinated and initially grown in a greenhouse at a neutral day length (12 hours of light), 17°C and a
472 minimum artificial light intensity of 150 $\mu\text{mol}/\text{m}^2\text{s}$. To ensure that individual plants were at comparable
473 developmental stages at sampling, the onset of treatment for different species was based on developmental
474 stages rather than absolute time. Most importantly, none of the plants had transitioned from vegetative to
475 generative phase, as this could have affected the cold response. Plants were grown until three to four leaves
476 had emerged for *M. nutans*, *S. lagascae*, *B. distachyon* and *H. vulgare*, or six to seven leaves for *N. stricta*
477 (which is a cushion forming grass that produces many small leaves compared to its overall plant size).
478 Depending on the species, this process took one (*H. vulgare*), three (*B. distachyon* and *S. lagascae*), six (*M.*
479 *nutans*) or eight (*N. stricta*) weeks from the time of sowing. Subsequently, plants from all species were
480 randomized and distributed to two cold chambers with short day (8 hours of light), constantly 6°C and a
481 light intensity of 50 $\mu\text{mol}/\text{m}^2\text{s}$. Plants were kept in cold treatment for the duration of the experiment. Leaf
482 material for RNA isolation was collected i) in the afternoon (at zeitgeber (ZT) 8) on the day before cold
483 treatment (D0) and in the afternoon (ZT 8) on the first day of cold treatment (8 hours after initiation of cold
484 treatment, D1) and ii) in the morning (ZT 0) before cold treatment (W0), 4 weeks of cold treatment (W4)
485 and 9 weeks of cold treatment (W9) (Fig. S1). The sampling time points were chosen to be able to separate
486 chilling stress responses (first day of treatment) and long-term responses that represent acclimation to
487 freezing temperatures (4 and 9 weeks of treatment). Flash frozen leaves were individually homogenized
488 using a TissueLyser (Qiagen Retsch) and total RNA was isolated (from each leaf) using RNeasy Plant Mini
489 Kit (Qiagen) following the manufacturer’s instructions. The purity and integrity of total RNA extracts was
490 determined using a NanoDrop 8000 UV-Vis Spectrophotometer (Thermo Scientific) and 2100 Bioanalyzer
491 (Agilent), respectively. For each time point, RNA extracts from five leaves sampled from five different
492 plants were pooled and sequenced as a single sample. In addition, replicates from single individual leaves
493 were sequenced for selected timepoints (see Table S1 and “Differential expression” below). Two time
494 points lacked expression values: W9 in *B. distachyon* (RNA integrity was insufficient for RNA sequencing)
495 and W0 in *S. lagascae* (insufficient supply of plant material). Samples were sent to the Norwegian
496 Sequencing Centre, where strand-specific cDNA libraries were prepared and sequenced (paired-end) on an
497 Illumina HiSeq 2000 system. The raw reads are available in the ArrayExpress database
498 (www.ebi.ac.uk/arrayexpress) under accession number E-MTAB-5300.

499 Transcriptome assembly and ortholog inference

500 Using Trimmomatic v0.32 (Bolger et al., 2014), all reads were trimmed to a length of 120 bp, Illumina
501 TruSeq adapters were removed from the raw reads, low quality bases were trimmed using a sliding window
502 of 40 bp and an average quality cut-off of 15, and reads below a minimum length of 36 bp were discarded.
503 Read quality was checked using fastqc v0.11.2. For each species, transcripts were assembled *de novo* with
504 Trinity v2.0.6 (Grabherr et al., 2011) (strand specific option, otherwise default parameters) using reads from
505 all samples. We assessed the completeness of the transcriptomes using Benchmarking of Universal Single-
506 Copy Orthologs (BUSCO) v3.0.2 (Waterhouse et al., 2018) with the provided Embryophyta database, based
507 on OrthoDB version 9 (Zdobnov et al., 2017) (Table S6). Coding sequences (CDS) were identified using
508 TransDecoder rel16JAN2014 (Haas et al., 2013). Where Trinity reported multiple isoforms, only the
509 longest CDS was retained. Ortholog groups (OGs) were constructed from the five *de novo* transcriptomes
510 and public reference transcriptomes of *H. vulgare* (barley_HighConf_genes_MIPS_23Mar12), *B.*
511 *distachyon* (brachypodium v1.2), *O. sativa* (rap2), *Z. mays* (ZmB73_5a_WGS), *S. bicolor* (sorghum 1.4)
512 and *L. perenne* (GenBank TSA accession GAYX01000000) using OrthoMCL v2.0.9 (Li et al., 2003). All
513 reference sequences except *L. perenne* were downloaded from [http://pgsb.helmholtz-](http://pgsb.helmholtz-muenchen.de/plant/plantsdb.jsp)
514 [muenchen.de/plant/plantsdb.jsp](http://pgsb.helmholtz-muenchen.de/plant/plantsdb.jsp).

515 High confidence ortholog groups

516 To compare gene expression across Pooideae, we required ortholog groups to contain one gene from each
517 species that all descended from a single gene in the Pooideae ancestor. As the ortholog groups (OGs)
518 inferred using orthoMCL sometimes cluster more distantly related homologs as well as include both
519 paraphyletic and monophyletic paralogs, we further refined the OGs by phylogenetic analysis. Several
520 approaches to phylogenetic refinement have been proposed previously (see e.g. Yang and Smith, 2014).
521 Here we first aligned protein sequences within each OG using mafft v7.130 (Katoh and Standley, 2013)
522 and then converted these protein alignments to codon alignments using pal2nal v14 (Suyama et al., 2006).
523 Gene trees were then constructed from the codon alignments using Phangorn v1.99.14 (Schliep, 2011)
524 (maximum likelihood GTR+I+G). Trees with apparent duplication events before the most recent common
525 ancestor of the included species were split into several trees. This was accomplished by identifying in-group
526 (Pooideae) and out-group (*Z. mays*, *S. bicolor* and *O. sativa*) clades in each tree, and then splitting the trees
527 so that each resulting sub-tree contained a single out-group and a single in-group clade. Finally, we only
528 retained the trees where all species in the tree formed one clade each (i.e. only monophyletic paralogs), *B.*
529 *distachyon* and *H. vulgare* formed a clade and at least three of the five studied species were included. These
530 trees constituted the high confidence ortholog groups (HCOGs).

531 Differential expression

532 Reads were mapped to the *de novo* transcriptomes using bowtie v1.1.2 (Langmead et al., 2009), and read
533 counts were calculated with RSEM v1.2.9 (Li et al., 2011). We observed higher numbers of monophyletic
534 species-specific paralogs in the *de novo* assembled transcriptome than in the reference genomes of *H.*
535 *vulgare* and *B. distachyon*. Since the *de novo* assembly procedure thus seemed to overestimate the number
536 of paralogs (most likely because alleles or alternative transcript isoforms were assembled into separate
537 contigs), we chose to represent each species in each HCOG by a single read-count value equal to the sum
538 of the expression of all assembled paralogs (analogous to so called monophyly masking (Smith et al.,
539 2011)). By additionally setting counts for missing orthologs to zero, we created a single cross species
540 expression matrix with HCOGs as rows and samples as columns (Table S3).

541 To identify conserved and diverged cold response across species, differentially expressed genes (DEGs)
542 were identified using DESeq2 v1.6.3 (Love et al., 2014) with a linear regression model that combined the
543 species factor and the time point factor (with time points W4/9 as a single level). Pooled samples provided
544 robust estimates of the mean expression in each time point. To also obtain robust estimates of the variance,
545 the model assumed common variance across all time points and species within each HCOG, thus taking
546 advantage of both biological replicates available for individual time points within species and the
547 replication provided by analyzing several species. For each species, we tested the expression difference
548 between D0 and D1 (short-term response) and the difference between W0 and W4/9 (long-term response)
549 (Fig. S1). *B. distachyon* lacked the W9 samples and long-term response was therefore based on W4 only.
550 *S. lagascae* lacked the W0 sample and long-term response was therefore calculated based on D0. Due to
551 the observed diurnal effect (Fig. S2A), this might have resulted in more unreliable estimates of the long-
552 term cold response in *S. lagascae*. Genes with a false discovery rate (FDR) adjusted p-value < 0.05 and a
553 fold change > 2 or < 0.5 were classified as differentially expressed.

554 Sample clustering

555 Sample clustering was based on read counts normalized using the variance-stabilizing transformation
556 (VST) implemented in DESeq2. The purpose of the VST-transformation is to create expression values
557 where the variability is not related to the mean. For large counts, these VST-values are equal to log2-
558 transformed values. HCOGs that lacked orthologs from any of the five species, or that contained orthologs
559 with low expression (VST < 3), were removed, resulting in 4981 HCOGs used for the clustering. To

560 highlight the effect of the cold treatment over the effect of expression level differences between species,
561 the expression values were normalized per gene and species: First, one expression value was obtained per
562 time point per gene by taking the mean of the replicates. Then, these expression values were centered by
563 subtracting the mean expression of all time point. Distances between all pairs of samples were calculated
564 as the sum of absolute expression difference between orthologs in the 4981 HCOGs (i.e. manhattan
565 distance). The sample clustering tree (Figure S2A) was generated using neighbor-joining (Saitou and Nei
566 1987).

567 Comparison with known cold responsive genes

568 Genes identified as short-term cold responsive in *H. vulgare* were acquired from supplementary table S10
569 in (Greenup et al., 2011). These genes were found to be responsive to cold in three independent experiments
570 with Plexdb accessions BB64 (Svensson et al., 2006), BB81 (no publication) and BB94 (Greenup et al.,
571 2011). The probesets of the Affymetrix Barley1 GeneChip microarray used in these studies were blasted
572 (blastx) against all protein sequences in our OGs. Each probe was assigned to the OG with the best match
573 in the *H. vulgare* reference. If several probes were assigned to the same OG, only the probe with the best
574 hit was retained. Correspondingly, if a probe matched several paralogs within the same OG, only the best
575 match was retained. DESeq2 was used to identify short-term response DEGs for all transcripts in all OGs
576 (i.e. this analysis was not restricted to the HCOGs), and these were compared to DEGs from (Greenup et
577 al., 2011). The statistical significance of the overlap between our results and those reported in (Greenup et
578 al., 2011) was assessed for each species by counting the number of genes that had the same response (up-
579 or down-regulated DEGs) and comparing that to a null distribution. The null distribution was obtained from
580 equivalent counts obtained from 100 000 trials where genes were randomly selected from all expressed
581 genes (mean read count > 10) with an ortholog in *H. vulgare*.

582 Gene ontology enrichment tests

583 Gene Ontology (GO) annotations for *B. distachyon* were downloaded from Ensembl Plants Biomart and
584 assigned to the HCOGs. The TopGO v2.18.0 R package (Alexa and Rahnenfuhrer, 2010) was used to
585 calculate statistically significant enrichments (Fisher's exact test, $P < 0.05$) of GO biological process
586 annotations in each set of branch specific DEGs using all annotated HCOGs as the background. The
587 enrichment analysis was restricted to a subset of GO terms relevant to plants (i.e. plant GO plant). Branch
588 specific DEGs were those genes that were exclusively differentially expressed in all species within a clade
589 in the phylogenetic tree.

590 Positive selection tests

591 To test for positive selection, we first identified a species tree topology. HCOGs with a single ortholog
592 from each of the five Pooideae species and *O. sativa* were used to infer gene trees. BEAST v1.7.5
593 (Drummond and Rambaut, 2007) was run with an HKY + Γ nucleotide substitution model using an
594 uncorrelated lognormal relaxed clock model. A Yule process (birth only) was used as prior for the tree and
595 monophyly of the Pooideae was constrained. MCMC analyses were run for 10 million generations and
596 parameters were sampled every 10.000 generation. For each gene tree analysis, the first 10 percent of the
597 estimated trees were discarded and the remaining trees were summarized to a maximum clade credibility
598 (MCC) tree using TreeAnnotator v1.7.5. The four most supported gene tree topologies are shown in Fig.
599 S4. The placement of the lineages Meliceae and Stipeae within the Pooideae species tree is uncertain. The
600 species tree topology used in the positive selection tests was equal to the most common topologies among
601 the 3914 MCC trees.

602 Each of the HCOG gene trees were tested for positive selection using the branch-site model in codeml,
603 which is part of PAML v4.7 (Yang, 2007). We only tested branches for positive selection in HCOGs

604 meeting the following criteria: (i) The tested branch had to be an internal branch also in the gene tree (i.e.
605 there was at least two species below the branch). (ii) The species below and above the tested branch in the
606 gene tree had to be the same as in the species tree or a subset thereof. (iii) The first species to split off under
607 the branch had to be the same as in the species tree (for the early split, either *S. lagascae* or *M. nutans* was
608 allowed). We then used the Hypergeometric test to identify statistically significant overrepresentation of
609 positive selection among branch specific DEGs (see “Gene ontology enrichment tests”) at the Pooideae
610 base (PB), the early split (ES) and the late split (LS) branches.

611 Gene family size and age

612 The gene family size was estimated as the number of genes in the OG divided by the number of species, i.e.
613 the average copy number per species in ortholog group. Family size was then plotted for each category of
614 differentially expressed genes (Figure S5). Error bars were computed as 95% confidence intervals of the
615 mean.

616 Gene-trees were downloaded from the Ensembl plants compara database (Herrero et al. 2016) and was used
617 to assign ortholog groups to phylostrata through matching *B. distachyon* gene IDs. The age of the root of
618 each ensembl gene tree was used as the phylostratum for the corresponding ortholog group. We used log
619 odds ratio to visualize the enrichment of cold response genes within each phylostratum (Figure S6).

620 Identification of candidate *de novo* transcripts and gene tree reconstruction

621 For five cold acclimation gene families (C-repeat binding factor genes (*CBFIII* and *CBFIV*), dehydrin genes
622 (*DHN*), chloroplast targeting cold-regulated genes (*ctCOR*), ice-recrystallization inhibition protein genes
623 (*IRIP*) and fructosyltransferase genes (*FST*)) we downloaded previously identified *H. vulgare* DNA coding
624 (*CDS*) and amino acid (AA) sequences (Table S5) from Genbank. The AA reference sequences were used
625 in protein BLAST searches against translated *de novo* transcripts. Potential candidate transcripts were
626 identified by discarding protein BLAST results with a maximum bitscore < 90, and e-value > 1E-21. When
627 at least one transcript met those criteria, all transcripts of the respective high confidence ortholog group
628 (HCOG) were defined as candidate transcripts. The HCOGs also contained reference CDS from the
629 Pooideae species *H. vulgare*, *L. perenne* and *B. distachyon* as well as from the outgroup species *O. sativa*,
630 *S. bicolor* and *Z. mays*. *De novo* transcripts not part of a HCOG were included when they met a maximum
631 bitscore > 110 and an e-value < 1E-31. MUSCLE v.3.8.31 (Edgar, 2004) was used to create initial multiple
632 sequence alignments (MSAs) by aligning all *de novo* candidate transcripts and reference CDSs with *H.*
633 *vulgare* Genbank CDSs and best BLAST hits for *Triticum* sp., *B. distachyon* and non-Pooideae CDS. To
634 reduce redundancy, reference CDSs were merged with Genbank CDSs when these were identical. To
635 ensure proper tree root resolution, additional outgroups were included where necessary.

636 After reconstructing an initial gene tree using PhyML (Guindon et al., 2010) assuming a HKY+ Γ nucleotide
637 substitution model, we removed sequences that were not part of the clade defined by Genbank CDS and
638 outgroup sequences. Subsequently we used CD-HIT-EST (available from <http://weizhongli-lab.org/cd-hit/>,
639 accessed 13.08.2018) to merge *de novo* transcripts from each species with a sequence identity > 90%.
640 Remaining intronic and non-coding regions were removed from the MSAs with exonerate v2.2.0 (Slater
641 and Birney, 2005). Additionally excluded fragmented *de novo* transcripts that were shorter than one third
642 of the Genbank CDS length. We produced a final MSA with MACSE v1.2 (Ranwez et al., 2011) setting *de*
643 *nov* transcripts as “less reliable sequences” and generated gene trees with PhyML applying a GTR+ Γ
644 model.

645 Acknowledgements

646 We thank Åsmund Bjørnstad, Ben Trevaskis and Mallikarjuna Rao Kovi for providing seeds of *H. vulgare*
647 “Igri”, “Sonja” and *L. perenne* “Fagerlin”, respectively. We thank USDA-NPGS GRIN for providing seeds
648 of *B. distachyon* and *S. lagascae*. For technical assistance handling plants during growth experiments we
649 thank Øyvind Jørgensen and Camilla Lorange Lindberg. We are grateful to Erica Leder, Thomas
650 Marcussen, Ursula Brandes and Camilla Lorange Lindberg for helpful comments on earlier versions of this
651 manuscript.

1002

1003 **Table 1. High confidence ortholog groups with conserved cold response in all five Pooideae.** These
 1004 16 genes had the same type of cold response (short- or long-term) in the same direction (up- or down-
 1005 regulation) in all five species. S = short-term response, L = long-term response. ↗ = up regulated, ↘ = down
 1006 regulated. Annotations were inferred from literature using orthologs.

Bd ortholog	Description and relation to stress response	Response
Bradi2g39230	HyperOSmolality-gated CA2+ permeable channel (OSCA) - Stress-activated calcium channels (Yuan et al., 2014) that are highly conserved in eukaryotes (Hou et al., 2014). In <i>Oryza sativa</i> , <i>OSCA</i> genes are differentially expressed in response to osmotic stress (Li et al., 2015).	S↗
Bradi2g06830	Calcium-binding EF-hand containing calcium exchange channel (EF-CAX) - Calcium ions are important mediators of abiotic stress in plants (Day et al., 2002; Bose et al., 2011). Expression of calcium binding proteins correlates with exposure to cold stress in several plants, e.g. <i>Arabidopsis thaliana</i> (Thomashow 1999), <i>Musa × paradisiaca</i> (Yang et al., 2015) and <i>Hordeum vulgare</i> (Greenup et al., 2011).	S↗
Bradi2g05226	GIGANTEA - Promotes flower development in plants (Andres and Coupland 2012). In <i>Arabidopsis thaliana</i> , this gene is involved in <i>CBF</i> -independent freezing tolerance (Cao et al., 2005; Xie et al., 2015), and is responsive to cold in <i>Zea mays</i> (Sobkowiak et al., 2014). Also part of the circadian clock.	S↗
Bradi4g24967	Arabidopsis Pseudo-Response Regulator 3-like (AtPRR3-like) - <i>AtPRR3</i> is a member of the circadian clock quintet <i>AtPRR1/TOC1</i> (Murakami-Kojima et al., 2002; Murakami et al., 2004). No association to stress response found in literature. However, <i>AtPRR3</i> -like might be closer related to <i>AtPRR5/9</i> than to <i>AtPRR3</i> (See Bradi4g36077, PRR95).	S↗
Bradi2g09060	Triacylglycerol lipase, alpha/beta-Hydrolase superfamily - Studies in <i>Arabidopsis thaliana</i> (Wang et al., 2011) and <i>Ipomoea batatas</i> (Liu et al., 2014) suggest that genes with alpha/beta-Hydrolase domains respond to osmotic stress. In <i>Triticum monococcum</i> , triacylglycerol lipase was induced by pathogen stress (Guan et al., 2015).	S↗
Bradi2g07480	Late-Embryogenesis-Abundant protein 14 (LEA-14) - Responsive to drought, salt and cold stress in <i>Arabidopsis thaliana</i> (Kimura et al., 2003; Singh et al., 2005), <i>Betula pubescens</i> (Rinne et al., 1998) and <i>Brachypodium distachyon</i> (Gagne-Bourque et al., 2015).	S↗
Bradi1g04150	SNAC1-like / NAC transcription factor 67 - <i>NAC</i> transcription factors mediate abiotic stress responses. Osmotic stress increases the expression of <i>SNAC1</i> in <i>Oryza sativa</i> (Nakashima et al., 2012), <i>NAC68</i> in <i>Musa × paradisiaca</i> (Negi et al., 2015; Yang et al., 2015) and <i>NAC67</i> in <i>Triticum aestivum</i> (Mao et al., 2014).	S↗
Bradi4g36077	Pseudo-Response Regulator 95 (PRR95) - Homologous to conserved circadian clock gene <i>AtPRR5/9</i> (Murakami 2003; Campoli et al., 2012). <i>AtPRR5</i> gene is cold regulated in <i>Arabidopsis thaliana</i> (Lee et al., 2005) and <i>PRR95</i> is cold responsive in <i>Zea mays</i> (Sobkowiak et al., 2014).	S↗
Bradi2g43040	DnaJ chaperon protein - <i>DnaJ</i> co-chaperons are vital in stress response and has been found to be involved in maintenance of photosystem II under chilling stress and enhances drought tolerance in tomato (Wang et al., 2014; Kong et al., 2014).	S+L ↗
Bradi3g33080	Glycogenin GlucuronosylTransferase (GGT) - GGT belongs to the GT8 protein family (Yin et al., 2011). In <i>Oryza sativa</i> , OsGGT transcripts are induced in submerged plants and respond to various abiotic stresses except cold (Qi et al., 2005; Uddin et al., 2012).	L↗
Bradi1g04500	Major facilitator superfamily transporter - Association to stress response unknown.	L↗
Bradi3g14080	Glycosyl transferase - Association to stress response unknown.	L↗
Bradi1g35357	Uncharacterized membrane protein - Association to stress response unknown.	S↗
Bradi2g48850	Uncharacterized protein - Association to stress response unknown.	S↗
Bradi1g33690	Uncharacterized protein - Association to stress response unknown.	S↗
Bradi1g07120	Putative S-adenosyl-L-methionine-dependent methyltransferase - Association to stress response unknown.	L↘

1007

1008

1009 **Figure 1. The Pooideae phylogeny, present temperature data for focal species and paleotemperature.**
1010 A. Schematic phylogeny of the study species. The species phylogeny and dates are inferred from Schubert
1011 et al. (2018), except for *B. sylvaticum*, which was not included in the study. Placement and divergence date
1012 for *B. sylvaticum* is thus approximate. B. The range of the minimum temperature of the coldest month
1013 (WorldClim v1.4 dataset, Bioclim variable 6, 2.5 km² resolution (Hijmans et al., 2005)) of the species
1014 geographical distribution (source: www.gbif.org). C. Oxygen isotope ratios as a proxy for historical global
1015 temperature (Zachos et al., 2001; Mudelsee et al., 2014). The transition between Eocene and Oligocene is
1016 shaded.

1017 **Figure 2. Frost tolerance after cold acclimation.** Regrowth of nine acclimated and non-acclimated
1018 Pooideae species after exposure to three freezing temperatures (-4°C, -8°C and -12°C). Significant
1019 differences in regrowth between acclimated and non-acclimated plants are indicated by asterisks (***) $P \leq$
1020 .001, ** $P \leq 0.01$, * $P \leq 0.05$).

1021 **Figure 3. Gene Ontology enrichment and positive selection in branch specific cold responsive genes.**
1022 A. Gene ontology enrichment analysis of high confidence ortholog groups (HCOG) that were differentially
1023 expressed (DEGs) in all species (PB), only in species after *N. stricta* split off (ES) or only in *B. distachyon*
1024 and *H. vulgare* (LS) (* $P < 0.05$, ** $P < 0.01$, *** $P < 0.005$, Fisher's exact test). GO enrichments are
1025 shown for up- and down-regulated DEGs – not distinguishing between short and long term response. Both
1026 the number of annotated genes and the number of annotations were indicated for each set of branch specific
1027 DEGs. B. Positive selection at different stages in Pooideae evolution. The circles and numbers represent
1028 the HCOG gene trees that were tested for positive selection at each split. The inner blue circle and numbers
1029 below branches represent HCOGs with branch specific differential expression (i.e. genes that were cold
1030 responsive exclusively in the species under the respective branch) while the outer circles and numbers above
1031 branches represent all other HCOGs. The purple and red pie-slices represent the proportions of HCOGs
1032 (first number) with positive selection ($P < 0.05$) among the total amount of tested HCOGs (second number).
1033 The P-values indicate the overrepresentation of positive selection among the branch specific DEGs
1034 (Hypergeometric test).

1035 **Figure 4. Summary of phylogenetic analyses and gene expression experiments.** Emergence of protein
1036 motifs and expansion of gene families important for cold acclimation are displayed on a schematic Pooideae
1037 species tree. The right-hand panel depicts expression profiles of *de novo* transcripts in response to long-
1038 and short-term cold of the respective species in the species tree. Expression patterns are approximated from
1039 the literature for *L. perenne* (*CBF* (Tamura and Yamada 2006), *WCS19/COR14* (Oishi et al., 2010; Ergon
1040 et al., 2016), *FST* (Hisano et al., 2008; Paina et al., 2014)) and *O. sativa* (*DHN8* (Lee et al., 2005), *DHN13*
1041 (Aguan et al., 1991) and *ctCOR*-like (Maruyama et al., 2014)).

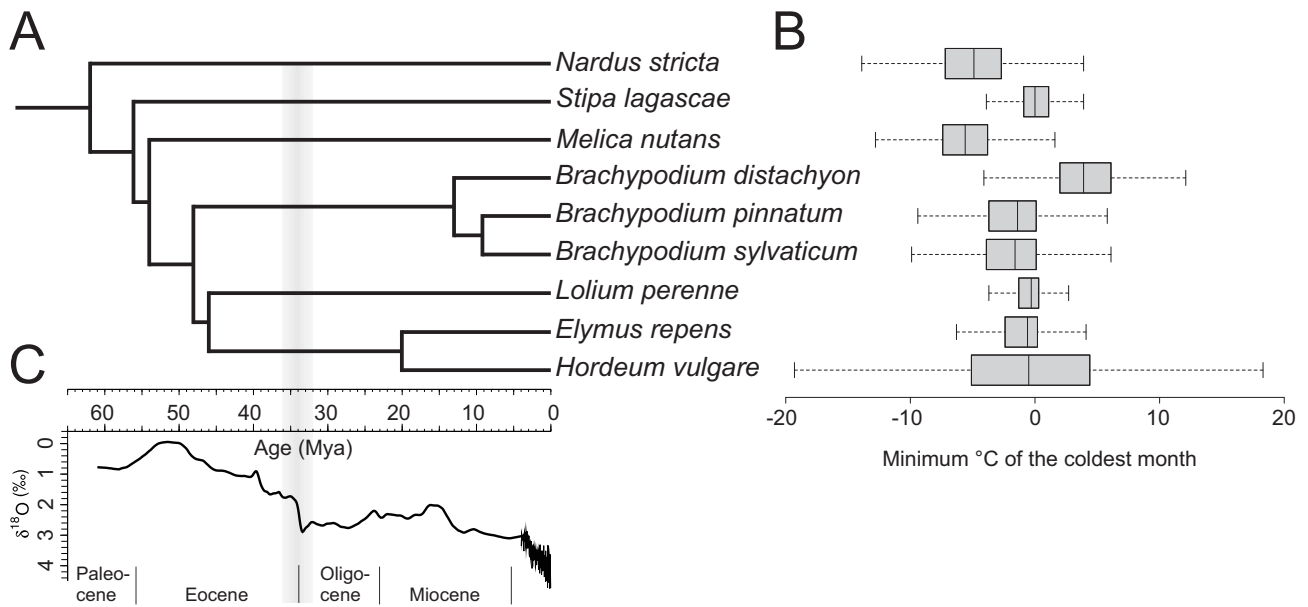

Figure 1. The Pooideae phylogeny, present temperature data for focal species and paleotemperature.

A. Schematic phylogeny of the study species. The species phylogeny and dates are inferred from Schubert et al. (2018) except for *B. sylvaticum*, which was not included in the study. Placement and divergence date for *B. sylvaticum* is thus approximate. B. C. Oxygen isotope ratios as a proxy for historical global temperature (Zachos et al., 2001; Mudelsee et al., 2014). The transition between Eocene and Oligocene is shaded.

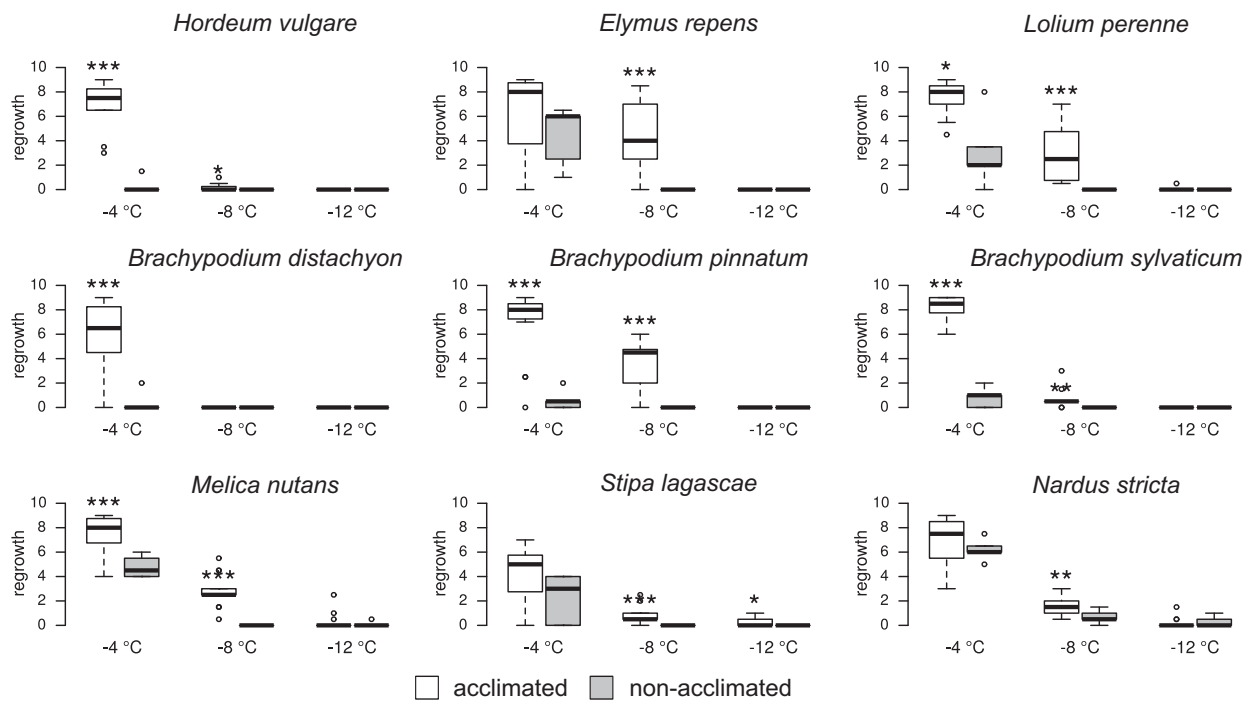

Figure 2. Frost tolerance after cold acclimation. Regrowth of nine acclimated and non-acclimated Poideae species after exposure to three freezing temperatures (-4°C, -8°C and -12°C). Significant differences in regrowth between acclimated and non-acclimated plants are indicated by asterisks (*** $p \leq 0.001$, ** $p \leq 0.01$, * $p \leq 0.05$).

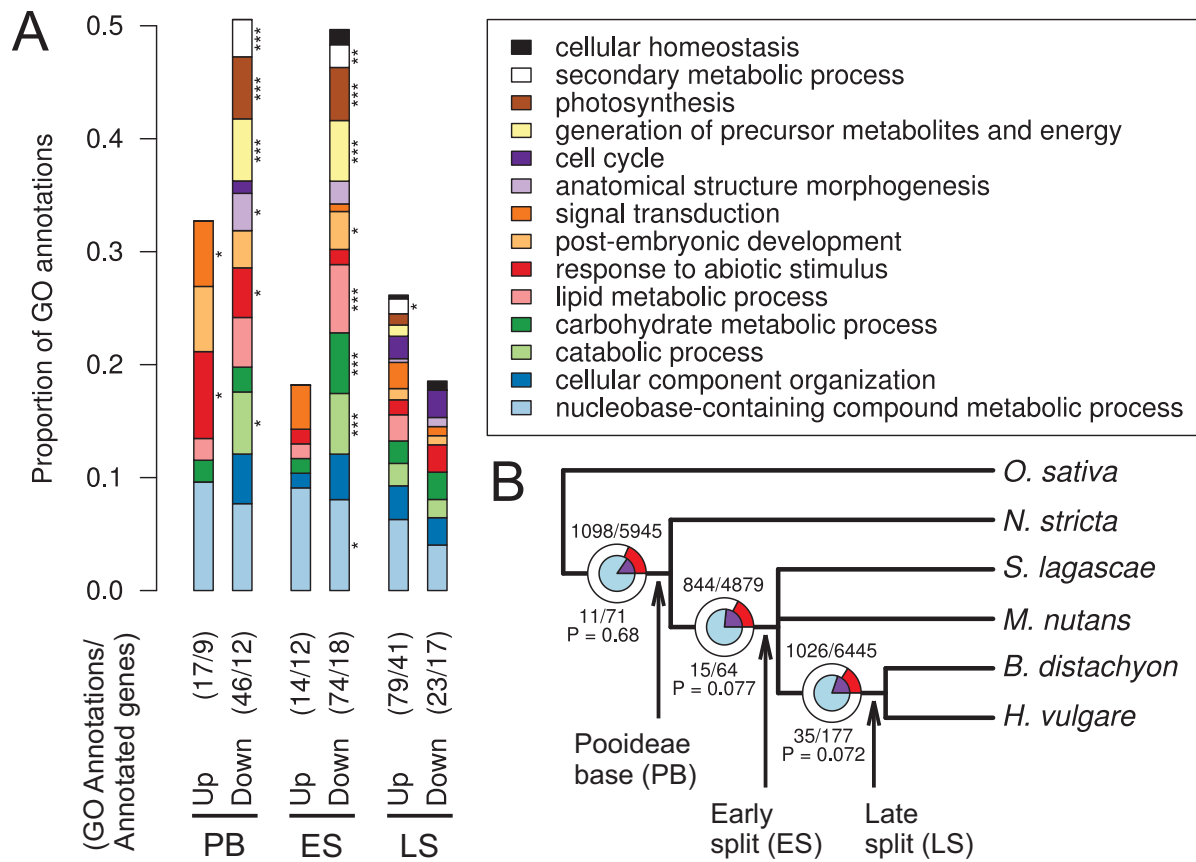

Figure 3. Gene Ontology enrichment and positive selection in branch specific cold responsive genes.

A. Gene ontology enrichment analysis of high confidence ortholog groups (HCOG) that were differentially expressed (DEGs) in all species (PB), only in species after *N. stricta* split off (ES) or only in *B. distachyon* and *H. vulgare* (LS) (* P < 0.05, ** P < 0.01, *** P < 0.005, Fisher's exact test). GO enrichments are shown for up- and down-regulated DEGs – not distinguishing between short and long term response. Both the number of annotated genes and the number of annotations were indicated for each set of branch specific DEGs.

B. Positive selection at different stages in Pooideae evolution. The circles and numbers represent the HCOG gene trees that were tested for positive selection at each split. The inner blue circle and numbers below branches represent HCOGs with branch specific differential expression (i.e. with genes that were cold responsive exclusively in the species under the respective branch) while the outer circles and numbers above branches represent all other HCOGs. The purple and red pie-slices represent the proportions of HCOGs (first number) with positive selection (P < 0.05) among the total amount of tested HCOGs (second number). The P-values indicated the overrepresentation of positive selection among the branch specific DEGs (Hypergeometric test).

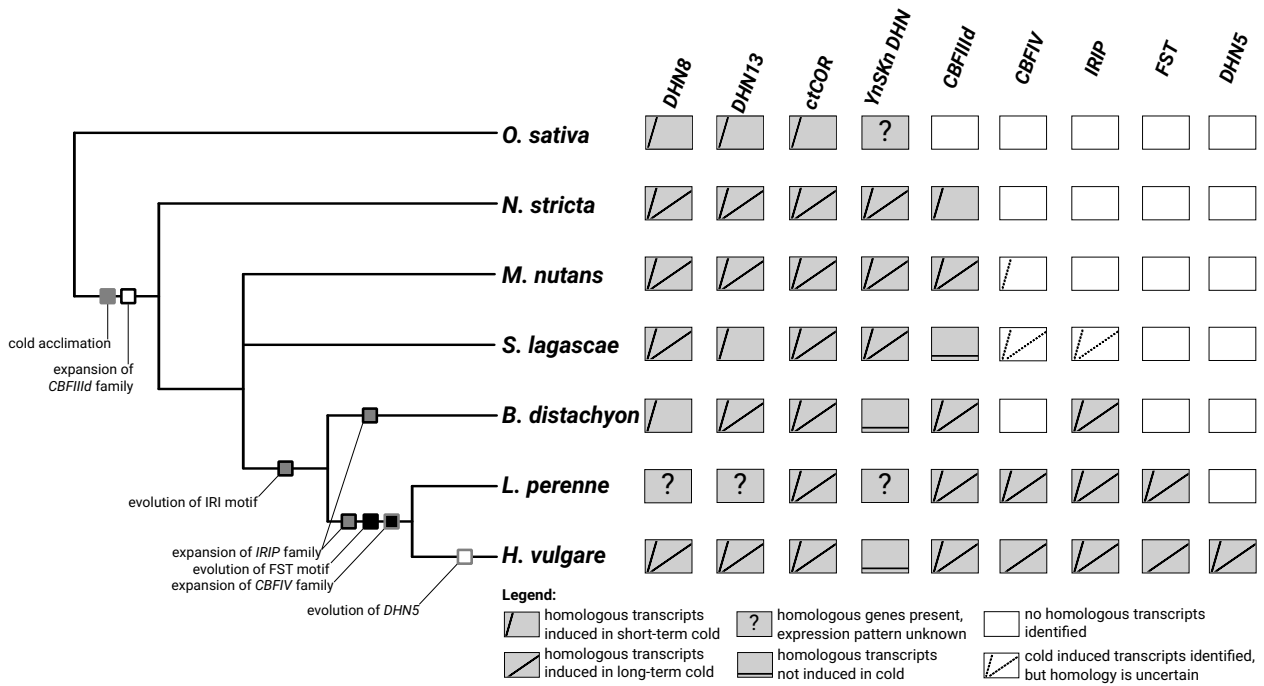

Figure 4. Summary of phylogenetic analyses and gene expression experiments. Emergence of protein motifs and expansion of gene families important for cold acclimation are displayed on a schematic Poideae species tree. The right-hand panel depicts expression profiles of de novo transcripts in response to long- and short-term cold of the respective species in the species tree. Expression patterns are approximated from the literature for *L. perenne* (CBF (Tamura and Yamada 2006), WCS19/COR14 (Oishi et al., 2010; Ergon et al., 2016), FST (Hisano et al., 2008; Paina et al., 2014)) and *O. sativa* (DHN8 (Lee et al., 2005), DHN13 (Aguan et al., 1991) and ctCOR-like (Maruyama et al., 2014)).

Supplementary figures

Figure S1. Experimental design. Plants from five species of Pooideae were subjected to a drop in temperature and shorter days to induce cold response. Leaf material was sampled on the day before the onset of cold (W0 and D0), once 8 hours after onset of cold (D1) and two times after 4 and 9 weeks of cold treatment (W4/W9). Short-term response was identified by contrasting gene expression in time points D0 and D1, while long-term response was identified contrasting W0 and W4/W9.

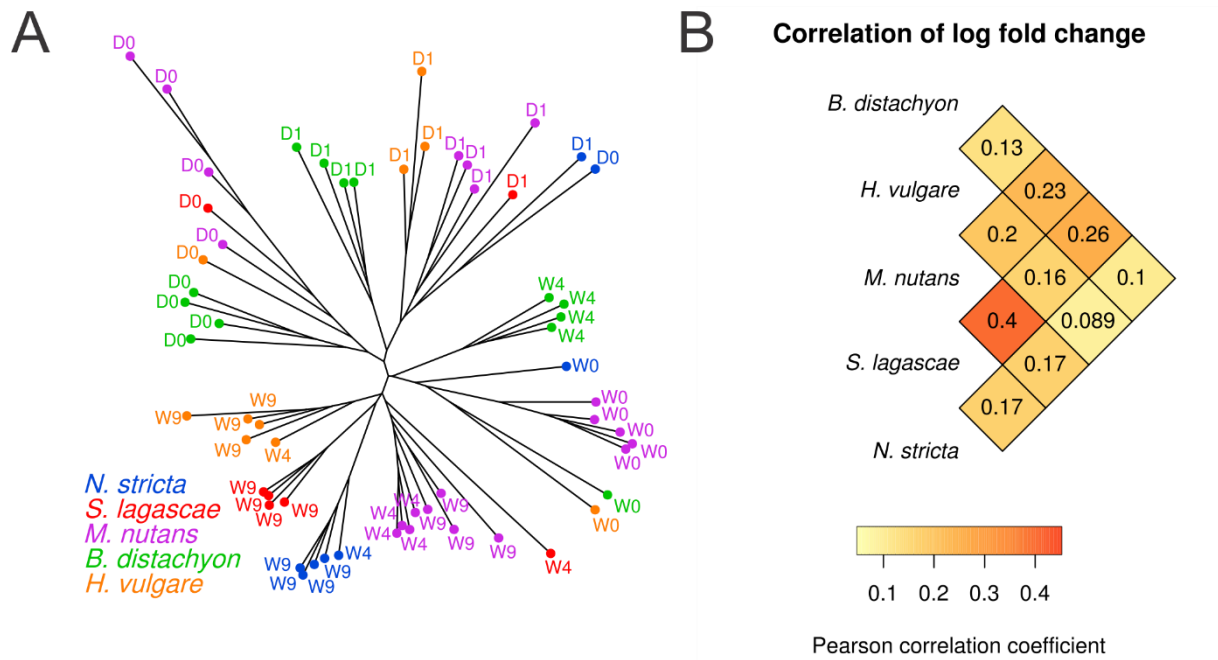

Figure S2. Comparison of cold response across the Poioideae. A. Expression clustering of the samples. The tree was generated by neighbor-joining of Manhattan distances between all pairs of species using highly expressed genes in high confidence ortholog groups (HCOGs) after subtracting the mean expression per species. Each tip corresponded to one sample. B. The Pearson correlations of log fold expression changes (i.e. log fold change in expression before and after cold treatment, only short-term cold response is shown here) between pairs of species. The correlations were computed based on the HCOGs.

Figure S3. Comparison of cold response to previous studies. A reference set of *H. vulgare* genes independently shown to respond to cold in several studies (Greenup et al., 2011) is compared to our data using short-term log fold change values. White cells represent missing orthologs. Grey cells represent orthologs that were not differentially expressed (not DEGs).

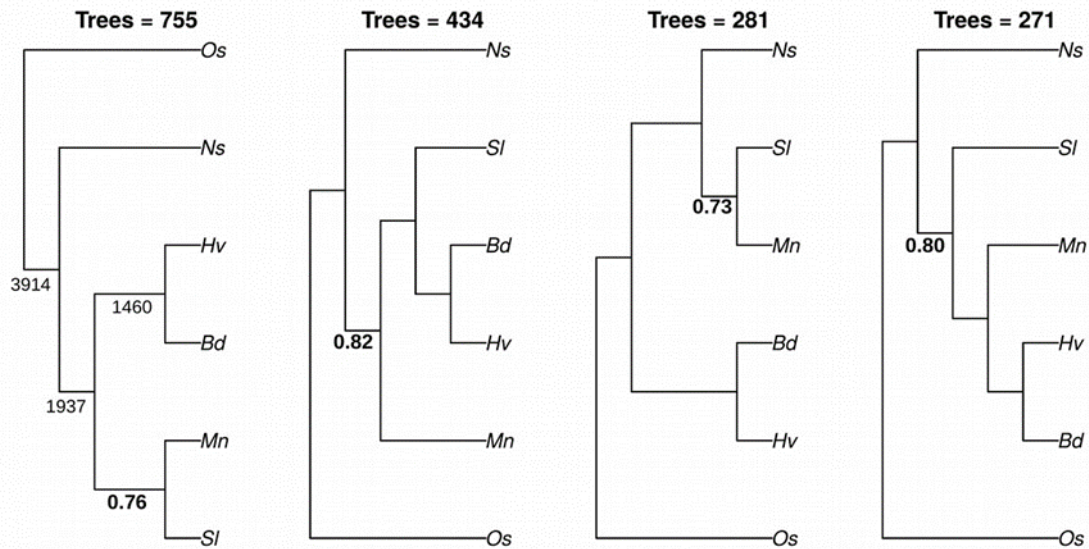

Figure S4: Gene tree topologies. We generated gene trees from a selected set of 3914 high confidence ortholog groups with one gene copy per species. The four most common topologies with mean posterior probabilities for the branches leading to the MRCA of *S. lagascae* and *M. nutans* are shown in bold. Integer numbers below the branches of the most common tree show how often the respective branch was represented among the 3914 trees.

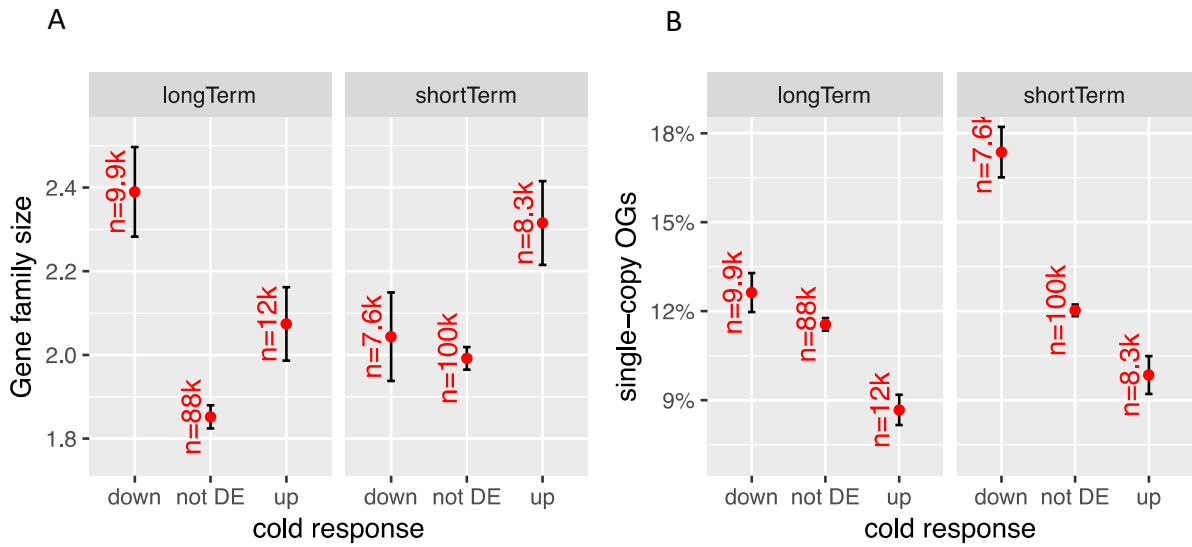

Figure S5. Association between cold response and gene family size. A. Response to cold is associated with larger gene family size. Gene family size is represented by the mean number of genes per species in each OG. Cold response is inferred by a differential expression test on all genes in all five species. The red dots indicate the mean family size of the genes in each cold response categories and the error bars indicate 95% confidence interval of the mean. B. Response to cold is associated with the proportion of OGs with single-copy genes in the five reference genomes *S.bicolor*, *Z.mays*, *O.sativa*, *B.distachyon* and *H.vulgare*. Error bars indicate 95% confidence interval

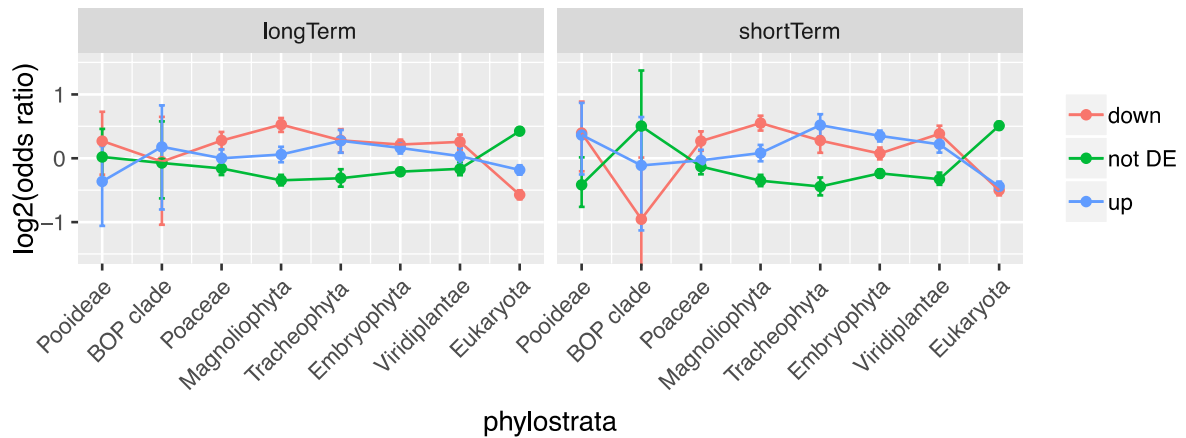

Figure S6. Phylostratigraphic analysis. Response to cold is associated with age of the gene family. Gene family age is represented by the phylostratum of the OG identified as the earliest lineage found within the corresponding Ensembl Plants gene tree. The odds ratio indicates an association between cold response and the phylostrata. A positive log odds ratio indicates enrichment of the cold response among the genes in the phylostratum. Error bars indicate 95% confidence interval generated by 1000 bootstraps.

Figure S7. Gene tree for C-repeat binding factors III (CBFIII) c/d group of the CBF gene family. Consistent with previous results (Badawi et al. 2007), our analysis reconstructs two well-supported Poideae-specific clades for *CBFIIIc* and *CBFIII d*. The *CBFIIIc* clade only contains one *de novo* transcript from *H. vulgare*, while the *CBFIII d* clade contains *de novo* transcripts from all studied species. Except *Stipa lagascae* all species possess *de novo* transcripts in the *CBFIII d* clade that are induced during cold treatment. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like approximate likelihood ratio test (aLRT), shown as branch labels, are considered significant ≥ 0.8 .

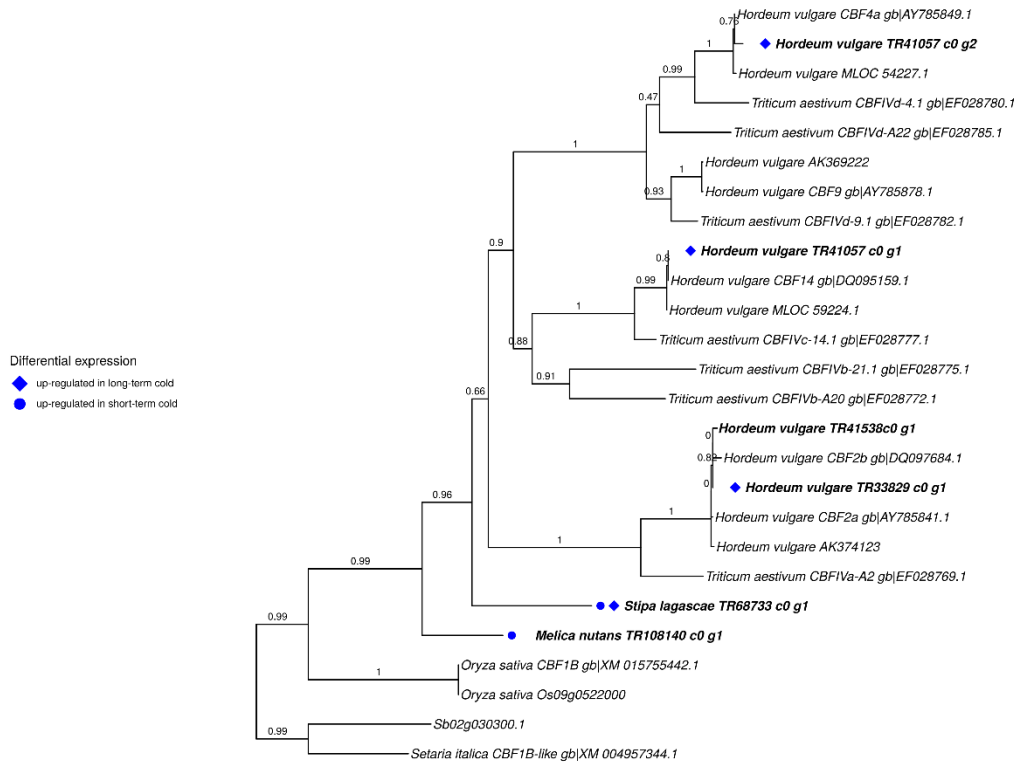

Figure S8. Gene tree for *CBFIV* group of the *CBF* gene family. Our analysis reconstructs four well-supported and previously described *CBFIV* clades specific to core Pooideae (Badawi et al. 2007), containing cold-induced *H. vulgare* transcripts. No homologous transcripts were identified for *N. stricta* or *B. distachyon*. Two cold induced transcripts from *S. lagascae* and *M. nutans* form a monophyletic clade together with the four core Pooideae *CBFIV* clades. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

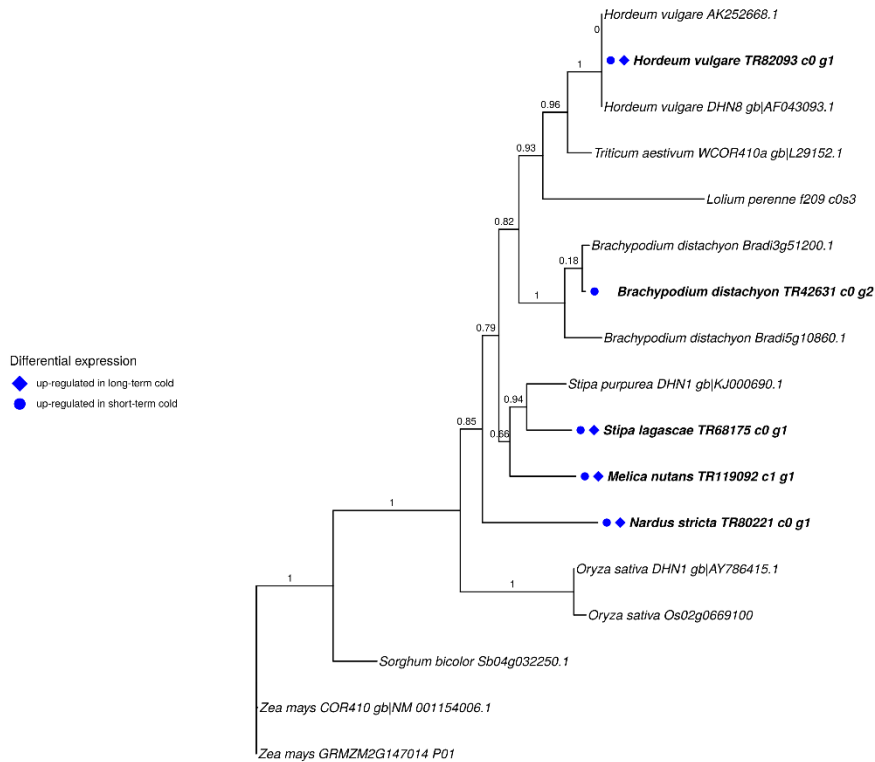

Figure S9. Gene tree for *Dehydrin 8 (DHN8)* gene. For *DHN8* gene we identified one cold induced *de novo* transcript in each studied species. Except for the transcript in *B. distachyon*, all transcripts were induced in short- and long-term cold. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

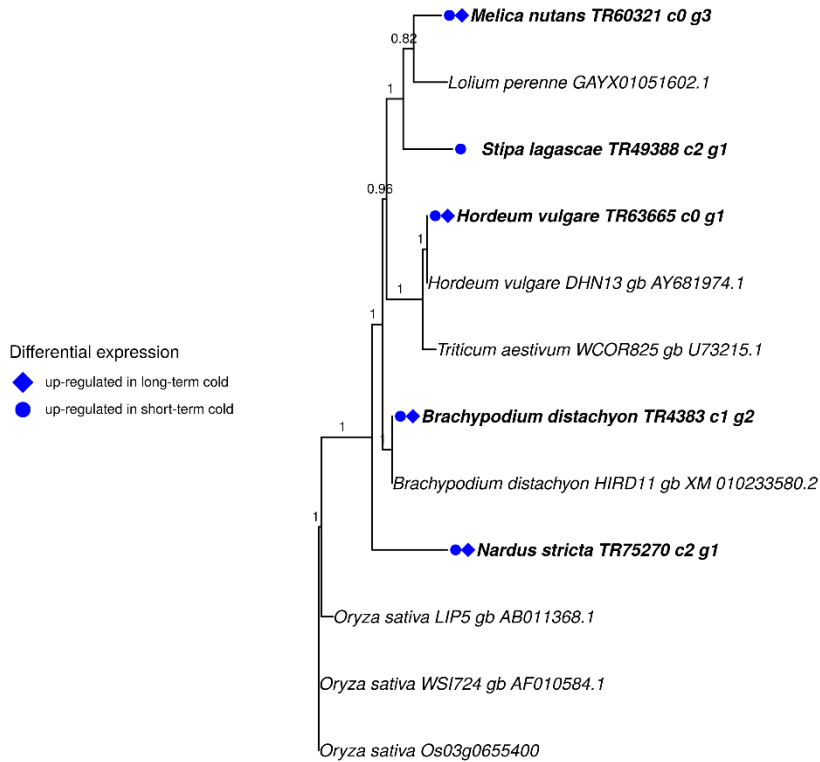

Figure S10. Gene tree for *DHN13* gene. For each of our study species we identified one cold induced *de novo* *DHN13* transcript. Except for the transcript in *S. lagascae*, all transcripts were induced in short- and long-term cold. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

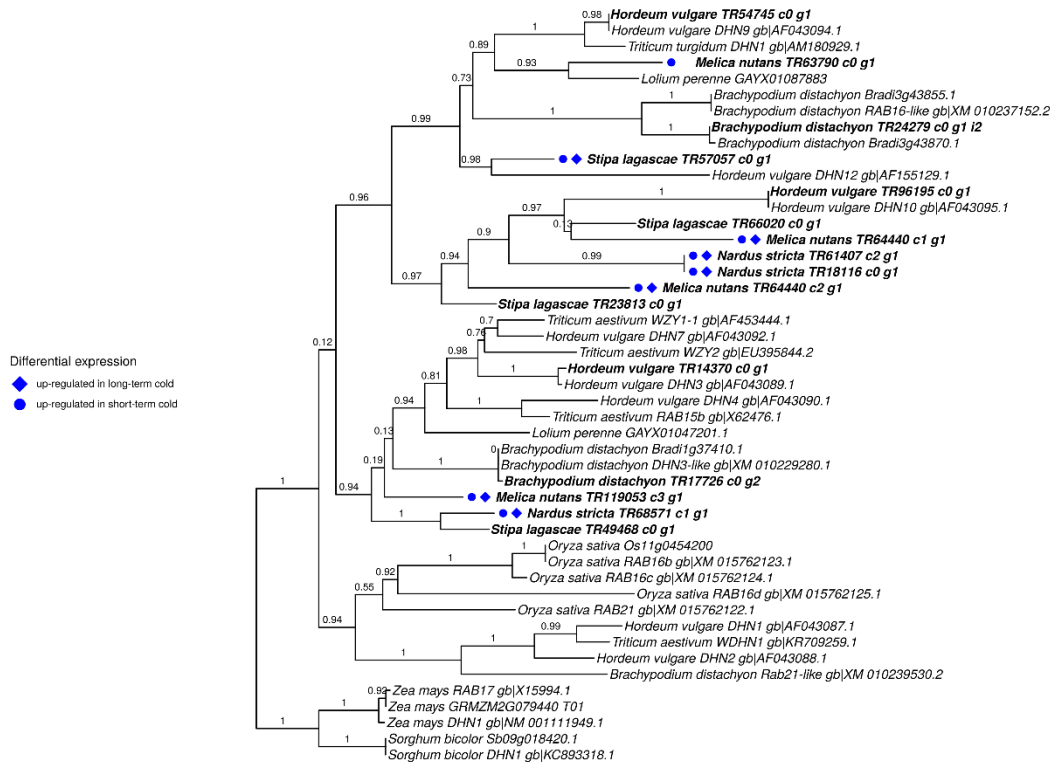

Figure S11. Gene tree for the Y_nSK_n -type *DHN* genes. Our analysis reconstructed a BOP-specific Y_nSK_n -type *DHN* clade, wherein we identified four, well-supported clades containing genes homologues to *HvDHN1-2*, *HvDHN9-12*, *HvDHN3-4-7* and *DHN10*. The latter three clades contained short- and long-term induced *de novo* transcripts of *N. stricta*, *S. lagascae* and *M. nutans*. Transcripts of *H. vulgare* and *B. distachyon* were not cold-induced. For the remaining Y_nSK_n -type *DHN* genes *HvDHN6* and *HvDHN11*, we did not identify any homologous transcripts, which is expected given that *HvDHN6* and *HvDHN11* are known to be expressed in embryos and caryopses only (Choi and Close 2000; Tommasini et al. 2008). These two genes were clearly less related to the rest of Y_nSK_n -type *DHN* homologs because they were nested outside the Poaceae-specific Y_nSK_n -type clade (data not shown). The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

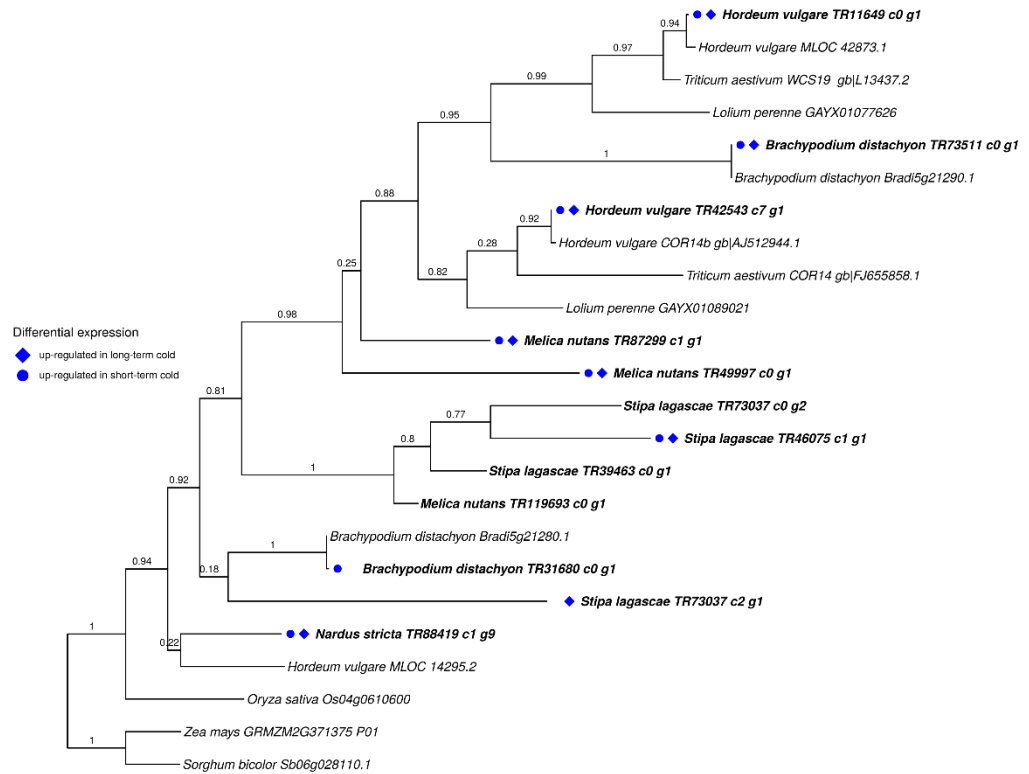

Figure S12. Gene tree for the *chloroplast-targeting cold regulated (ctCOR)* gene family. In all species we identified short- and long-term cold induced transcripts homologous to known *ctCOR* genes which formed a Pooideae-specific clade. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

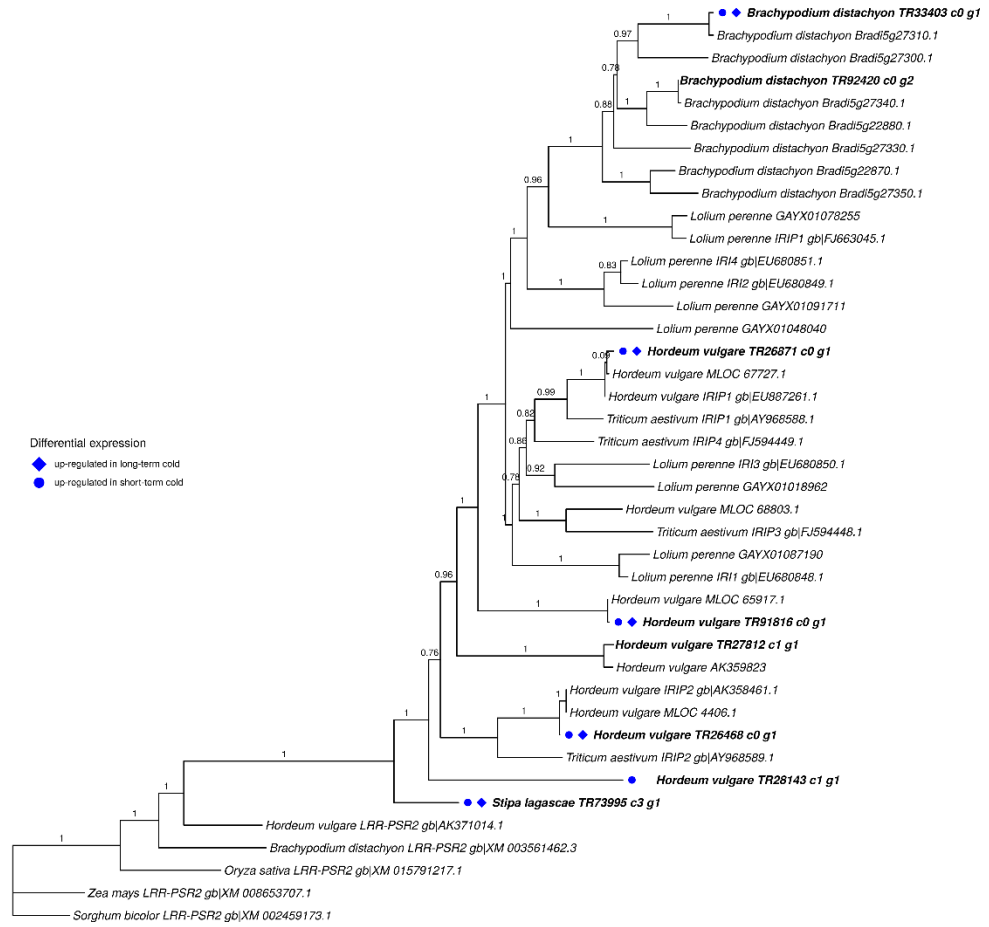

Figure S13. Gene tree for the *ice-recrystallization inhibition protein (IRIP)* gene family. We identified short- and long-term cold induced *IRIP* transcripts for *H. vulgare* and *B. distachyon* that formed a monophyletic clade with two cold-induced *IRIP*-like transcripts of *H. vulgare* and *S. lagascae* whose characteristic IRI-motif was truncated. No *IRIP* homologs were identified for *M. nutans* and *N. stricta*. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

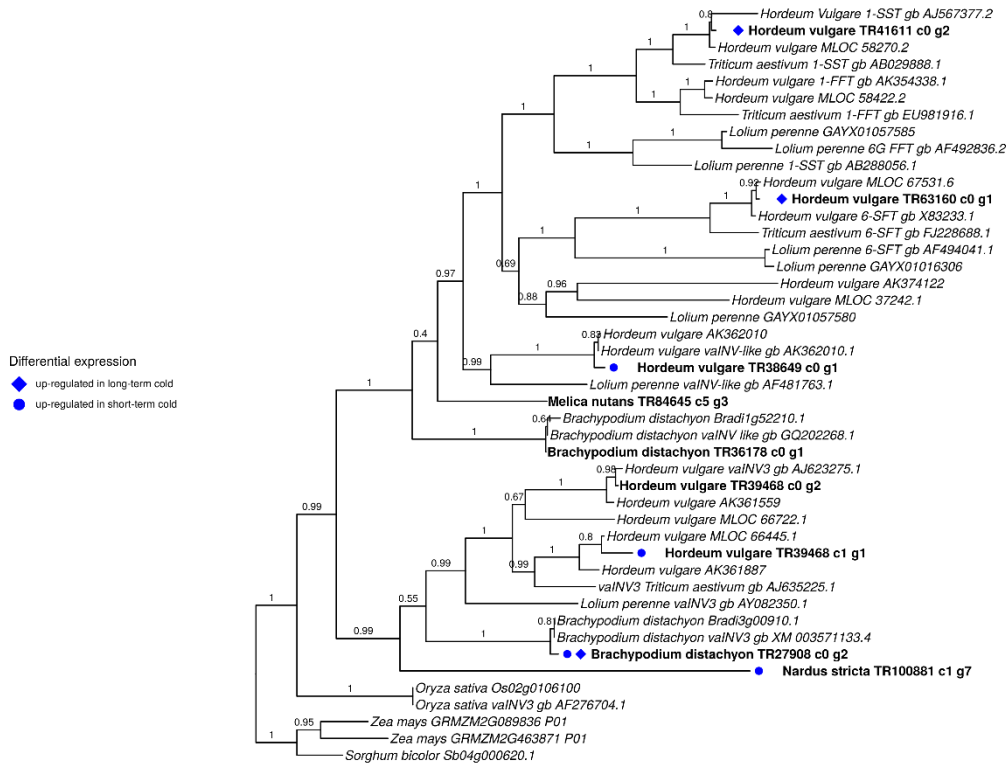

Figure S14. Gene tree for the *fructosyltransferase (FST)* gene family. We identified two long-term cold induced *H. vulgare* transcripts containing the characteristic FST motif. None of the other *de novo* transcript seemed to be FST homologs since they lacked this motif, except a short-term cold induced transcript of *N. stricta*, which however was nested within the *vacuolar invertase 3 (vaINV3)* clade. The phylogram was estimated with PhyML v3.1 using a GTR+ Γ substitution model. Estimates of a SH-like aLRT are shown as branch labels.

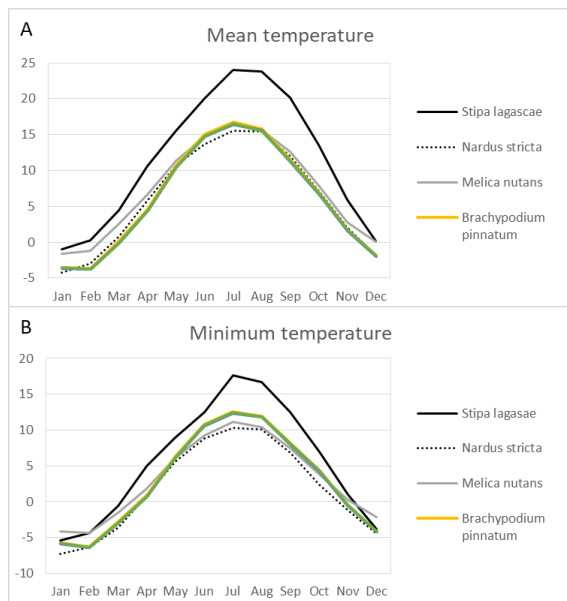

Figure S15. Climatic data. Climatic data for the sampling localities of the accessions used in the experiment of *Nardus stricta*, *Stipa lagascae*, *Melica nutans*, *Brachypodium pinnatum*, *B. sylvaticum* and *Elymus repens*. A. Mean temperature per month. B. Minimum temperature per month.

Table S2. High confidence ortholog groups (HCOGs). HCOGs generated by filtering and splitting ortholog groups (see Methods). Ortholog groups were stored as a table with the ortholog group IDs as rows and species as columns. Each cell contains sequence IDs separated by “,”. Groups that were the result of splitting larger ortholog groups were marked by a number suffix in the group ID.
